Overview

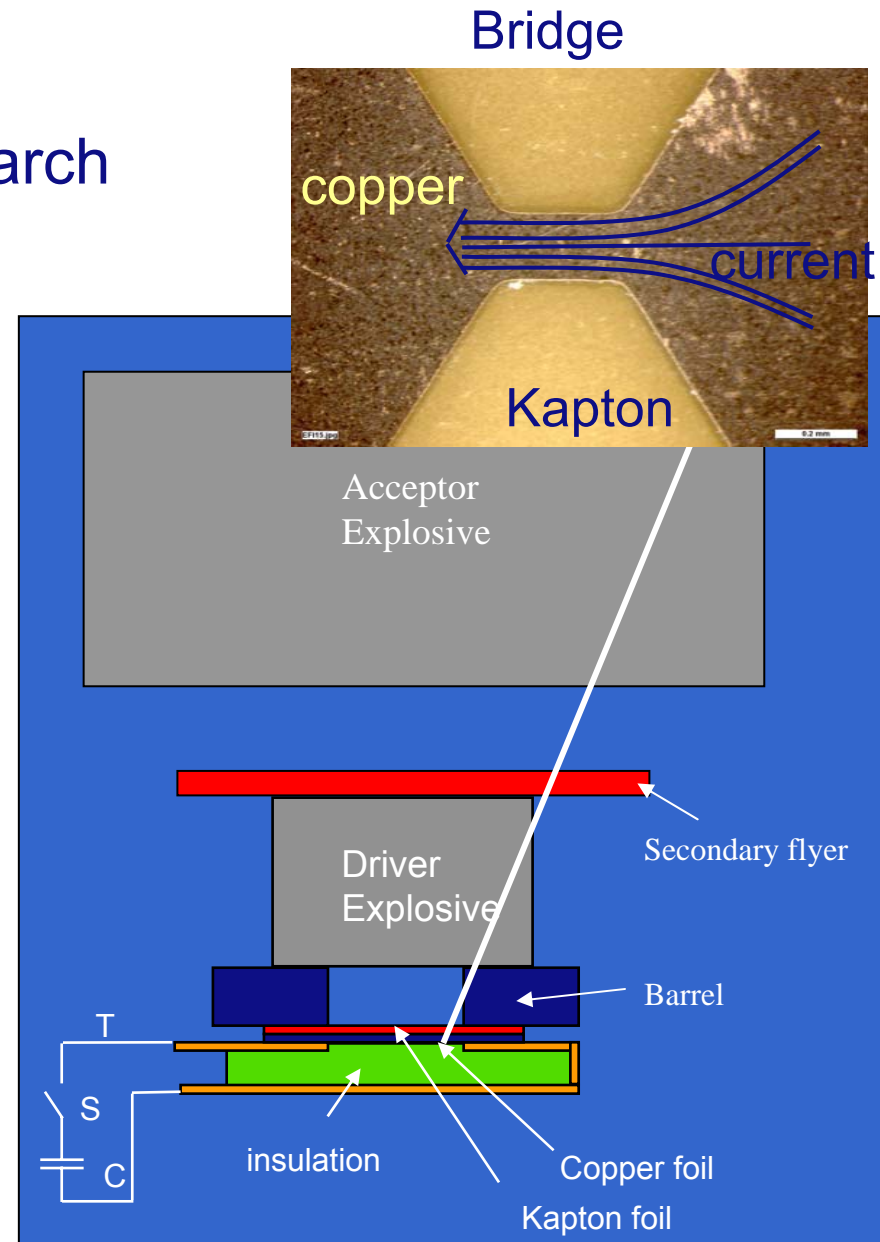

- Introduction
- Why EFI systems
- Exploding Foil Initiator Research
- Research on Explosives
- Conclusions

Introduction

Exploding Foil Initiator Research

- Exploding foil
- Electrical circuit
- Velocity of the flyer
- Driver Explosive
- Secondary flyer
- Acceptor explosive

Shock initiation research at TNO: Mega Ampere Pulsar and Flyer Impact

~4 feet

Wim Prinse

Why an EFI system

- An EFI is intrinsically safer than standard initiators (no primary explosive)
- More reliable (so hardly no UXO's)
- Works much faster < microseconds
- Can be smaller (near future)
- Is compliant with new STANAG (4560) regulations
- New opportunities (tandem charges, aim able warheads)

- Disadvantage : More expensive (at the moment)

- Future: Micro Chip EFI (McEFI) → inexpensive

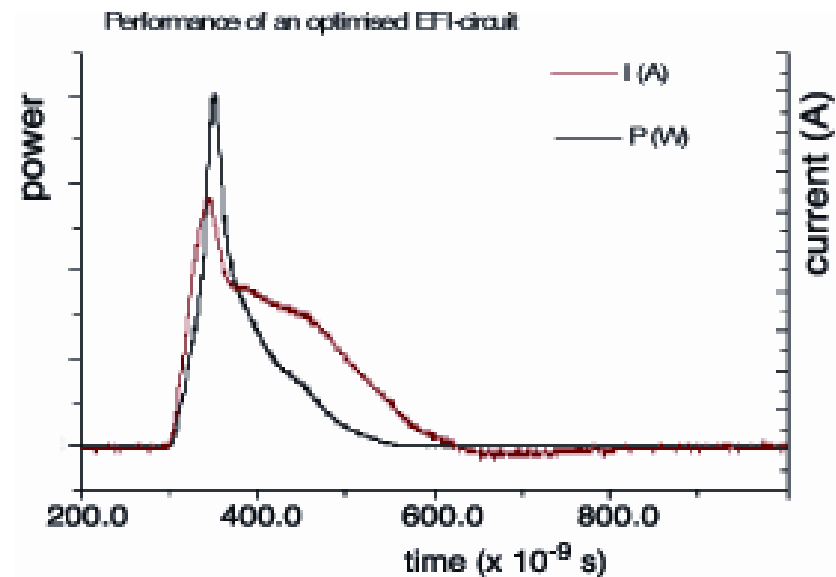

Exploding foil

- Dimension of the foil (length, width, thickness, form, material)
- Shockwave impedance of the tamper
- Thickness and material of the flyer
- Length and width of the barrel

Electrical circuit

- Optimisation of the circuit
 - low loss capacitor
 - Switch (solid state)
 - transmission line
- Development of measuring techniques (current, voltage, velocity of the flyer)
- 90 % efficiency of energy deposited in the exploding foil (50 % other circuits)

Fabry-Perot system

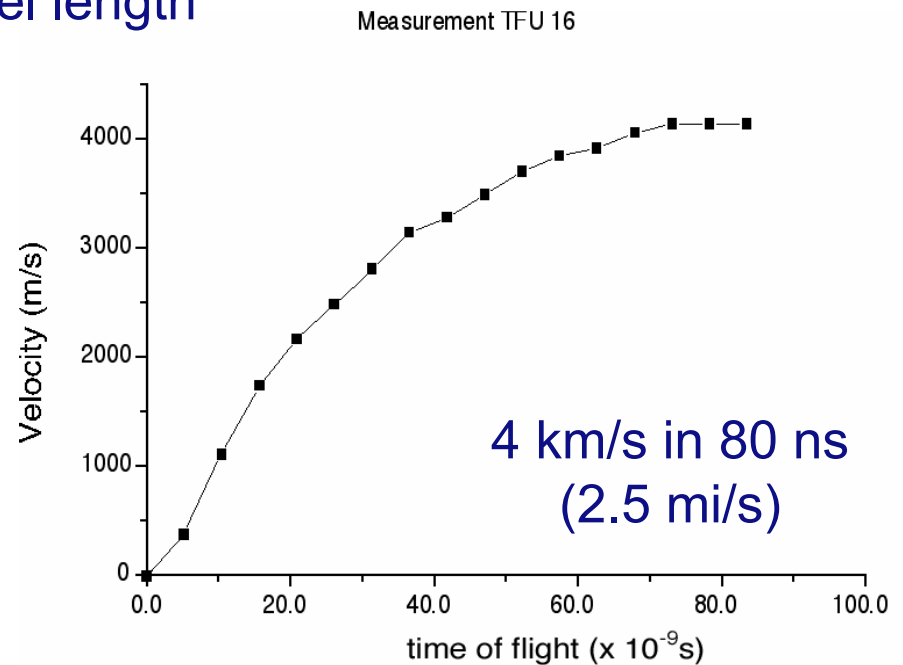

Fabry-Perot system

Flyer velocity measurement by F-P Interferometer

- Acceleration of the flyer influenced by:
 - thickness and material
 - exploding foil dimensions and material
 - shockwave impedance of the tamper
- Integrity of the flyer during acceleration
 - Determination of optimum barrel length

Research on Explosives I

- Recrystallisation of HNS II to HNS IV
- The crystals are more uniform (smaller distribution)
- The length to width to thickness is 10:3:2
a further increase in specific surface area is possible

Initiation behaviour of different explosives

- Different types of explosives
 - HNS IV several brands
 - TATB several grades
 - New explosives
- Initiation energy depends on flyer thickness and velocity

Initiation of 5 x 5 mm HNS IV pellet

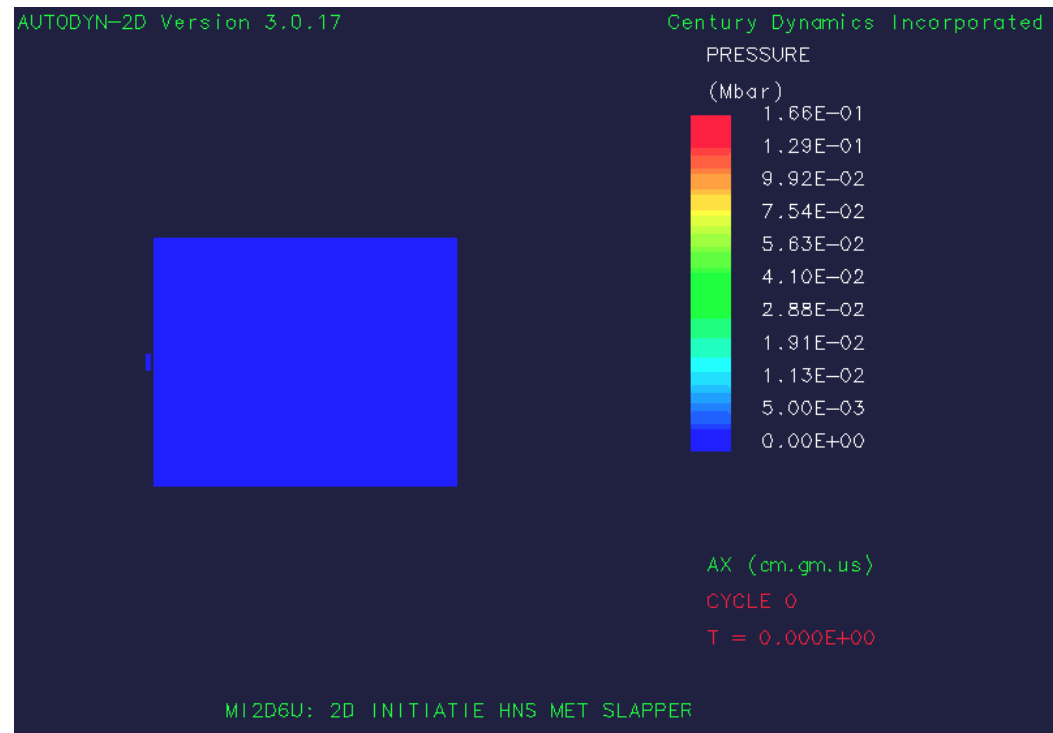

Voltage < 1300Volt

Transmission line

Numerical simulations of flyer impact

- Lee-Tarver model modified with visco-plastic pore collapse model
- Qualitatively the simulations can explain the experiments

Reacted fraction of HNS IV after initiation by 5.4 mm/ μ s flyer

Secondary flyer acceleration

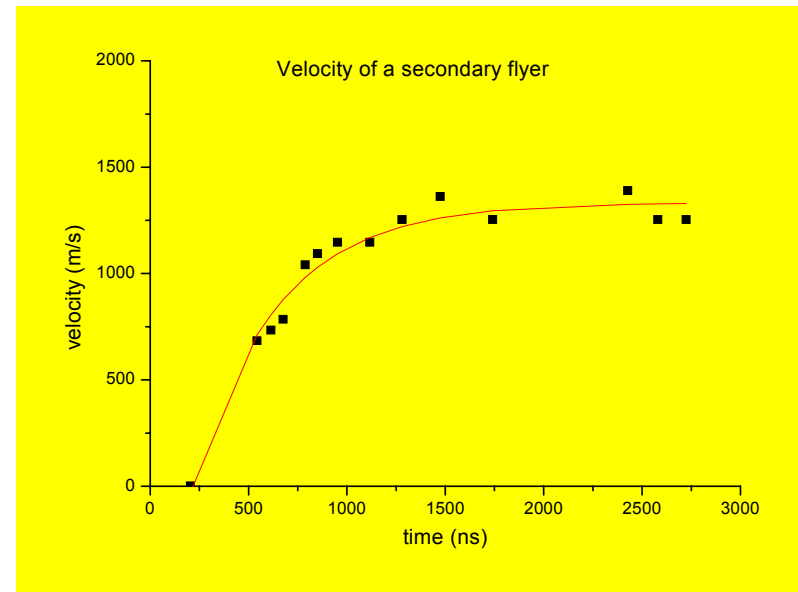

- Driver explosive (HNS IV), confined
- Secondary flyer material:
 - aluminium
 - stainless steel
 - kapton
 - mylar
- Important properties:
 - spall strength (attenuator)
 - shockwave impedance
 - size and thickness
- Velocity of flyer measured with Fabry-Perot Velocity Interferometer System

Secondary flyer impact

Acceleration of a 0.25 mm stainless steel flyer by HNS IV
Successful initiation of TATB and RDX by

- 0.15 mm SS steel flyer
- 0.35 mm mylar flyer
- 0.3 - 0.5 mm Al flyer

Development of mini EFI and developer platform for Micro Chip EFI (McEFI)

- Efficient Transmission line with exploding bridge
- Pressed HNS IV
- Electronic component of the shelf (capacitor, HV unit, solid state switch and some standard electronic components)
- Knowledge/experience

- Mini-EFI and developer platform for McEFI

Conclusions

- A very efficient electrical circuit ($\eta = 90\%$)
- Mini-EFI Works at Voltage lower than 1300 Volt (Solid state switch)
- With “of the shelf components” small IM compliant EFI-detonators can be build (8cm³ including High Voltage-supply)
- The use of secondary flyers makes the detonation train more reliable (in case of set-back)
- Combining the EFI with the ESAD with Micro Chip technology can make a small and cost effective unit
