## Bore Elevation and Azimuth Measurement System (BEAMS)

Prepared for Joint Armaments Conference, Exhibition & Firing Demonstration 17 May 2012  
by Robert P. Pinto, Fire Control Systems & Technology Directorate

- Designed in response to a request from the Naval Surface Warfare Center (NSWC), Crane Division and PM Mortars for
  - A low-cost means
  - Verify the **elevation and azimuth** weapon pointing accuracy requirements
    - Navy 81mm Mortar Fire Control
    - 120mm M150/M151 Mortar Fire Control Systems – Dismounted
  - In a field-test environment

**Bore Elevation and Azimuth Measuring Apparatus And Method**  
U.S. Patent 7,856,729 December 2010

<http://www.google.com/patents?q=7856729>

- Provides a means
  - For the fixture to self-center in the weapon tube
  - To calibrate and verify that the projection of the tube axis is coaxial to the tube axis
  - To measure and/or remove bias from the fixture
  - To make measurements
    - In elevation and azimuth
    - High accuracy
    - Utilizing conventional survey procedures
- All of which may be accomplished in an engineering field-test environment

- Artillery and mortar weapon azimuth pointing measurements used a fixture inserted in weapon tube
- The fixture extends the axis of the tube so it can be observed by a single theodolite
- The vertical reticle line of the theodolite must align to **both** the tip and lower reference point at the **same time**
  - Very difficult to do,
    - especially at high quadrant elevations

- Fixtures tend to be
  - Long
  - Subject to damage from bending
  - Cumbersome to use
- Alternatively a line is scribed on the outside of the weapon tube
  - Drawn parallel to the tube axis
  - Scribe lines are difficult to accurately establish
  - If the outer tube wall is not parallel to the tube axis
    - Tube cant measurements need to be made
    - Correction equations for non-parallelism of lines to the weapon axis need to be applied
- Sighting down the side of the weapon tube is also used but
  - It is difficult to do
  - Error prone since weapon tubes have varying cross sections

- Incorporates interchangeable lobes which
  - allow for use with any weapon tube caliber, and
  - spring loaded plungers and
  - non-marring brass pads which
  - allow the fixture to self-center on the weapon tube axis

- Mechanical adjustment allows laser aperture to be positioned on-axis with the weapon bore
  - Dial Indicator measures run-out as fixture is rotated in 180-degree increments
  - Mechanically adjust until run-out is eliminated

- Eye-safe AN/PEM-1 Laser provides projection of the tube axis
  - Designed for aligning sights on numerous weapon systems
  - Hundreds currently in-use
  - Designed to be viewed with magnifying optics
  - Contains integral up/down left/right beam adjustments

- Laser beam adjustment allows laser to be positioned on-axis with the weapon bore
  - Theodolite views run-out as fixture is rotated in 180-degree increments
  - Beam is adjusted until run-out is eliminated

- Two theodolites, T1 and T2, measure Horizontal (H) and Vertical (V) angles to:
  1. The other theodolite (once per set-up)
  2. The laser spot, P1, on the first screen
  3. The laser spot, P2, on the second screen
- Laser spots can be viewed on a simple paper or Mylar® screen or any convenient surface
- The horizontal angle to the point measured from the opposing theodolite is proportional to the distance
  - That is, the distance from T1 to P is proportional to H of T2
- The vector from each theodolite defines a 3-Dimensional XYZ coordinate of laser point P
- From two points, P1 and P2, the elevation and azimuth of the laser is established

Laser spots enhanced for clarity

- The computations are automated in an Excel® spreadsheet
- Output shows
  - Elevation,
  - Azimuth
  - Magnitudes of measurement errors
  - Intermediate computations
- If fixture is not calibrated -
  - Rotate laser fixture 180-degrees in the bore without moving the tube
  - Make another set of measurements
  - Average of before and after elevations and azimuths are the proper values

17 May 2012 (PR)

**TECHNOLOGY DRIVEN. WARFIGHTER FOCUSED.**

- Worked with PM Towed Artillery Systems to adapt BEAMS to the 105mm M119A2 Howitzer
  - Laser fixture for rifled cannon
  - Calibration and measurement procedures
  - Howitzer Onboard Optical Target Imaging Screen (HOOTIS)
  - Rear Yoke Position Laser (RYPL)
  - Trained Yuma Test Center (YTC) personnel in BEAMS operation

- LaserGlow Technologies  
LBS-532-TD-5 laser
  - Extremely high visibility
    - Green is 5-10 times more visible than a red laser
    - Green is not filtered-out by theodolite optics
  - Output power <5 mW
  - Low divergence at working distances

LBS-532-TD-5 Eye-safe Laser

- Howitzer Onboard Optical Target Imaging Screen
  - A convenient device to hold two translucent Mylar® screens
  - Screens are used to view the laser spot
  - Screen closest to muzzle flips up so laser can strike second screen
- HOOTIS is placed on the muzzle after laser is inserted in bore

## Rear Yoke Position Laser (RYPL pronounced ripple)

- Provides an independent check of the angular relationship between the Inertial Navigation Unit (INU) mounting plate and the cannon bore
- Utilizes Picatinny Rail for quick-release
- Angular deviation predicted failure of the rear yoke

## Paladin Laser Fixture

- Breech fixture using the same principles as original mortar fixture
- Three optical stages provide lateral adjustment in Y and X as well as pitch and yaw of the laser
- The optical stages are mounted on a circular plate
- Same LaserGlow Technologies laser proven on M119A2 Howitzer application

- Reverse side of plate supports
  - Three high-pull neodymium magnets contact cannon face
  - Three lobes contact the cannon wall
    - Two lobe assemblies machined to match the radius of the cannon bore
    - Third lobe fitted with a spring loaded plunger
    - Maintains self-centering of the fixture
  - Laser mechanical and optical run-out adjusted similar to the mortar fixture
  - Laser can be adjusted to 0-mils QE when cannon muzzle flat is at 0-mils

## Paladin HOOTIS

- Truss section weighs less than six pounds
- 12-foot distance between screens
- Mandrel allows HOOTIS to be rotated for better viewing

## Integrated BEAMS (iBEAMS)

- Incorporates direct digital communications between the control computer and each of the two theodolites
- Provides automatic data collection from each theodolite
- Directly populates data into the appropriate cells of the iBEAMS Excel workbook
- Eliminates human data transcription errors
- Greatly speeds the measurement process

DISTRIBUTION STATEMENT A: Approved for public release, distribution unlimited.

- A compact laser fixture
  - Accurately self-centers in weapon bore
  - Scales to any caliber weapon system
  - Calibration & verification that the projection of the tube axis is
    - Coaxial with the tube axis, or
    - At the same QE and azimuth
  - Includes a means to measure and/or remove bias from the laser fixture
- Theodolites may be placed at virtually any arbitrary position
  - Theodolites remain in the same place for all testing
- Provides a clearly defined theodolite aim point
  - Utilizes conventional surveying practices
  - Makes precision measurements with an accuracy greater than other current methods – 0.1-mils, 0.05 is achievable
  - Measures **elevation and azimuth** at the same time
