- VI. Conclusions/Further Work
- VII. Questions

- During the manufacturing process in 2011, 46 M119A2 systems were manufactured with a tooling groove defect in the 12593242 Cradle.
- The worst case tooling groove was 0.071-in deep and 2.300-in long, spanning the full length of the channel.

- **Goals:**

- Run a fatigue and critical crack analysis on the modeled portion of the plate that has the tooling defect (gouge).
- Determine if cradle will survive for 1100 cycles (per reliability requirement MIL-DTL-32191).
- Determine if further analysis is needed.

- **Scope:**

- The primary concern of the analysis effort is to analyze M119 cradle components specifically the firing mechanism plate of the cradle channel.
- The model is loaded by pressure data calculated from strain gauge data that was recorded during live fire testing.

***Note: Cradle critical components labeled, individual parts not specified below

Firing Mechanism Plate
(gouge flaw)

Rear cradle structure

Firing Mechanism attachment points

- Analysis was performed using Abaqus 6.11
 - Analyses types: Dynamic implicit (XFEM) and explicit, non-linear materials, non-linear geometry
 - All models were meshed with 8-node hexahedral elements (C3D8R).
- To simulate the fixed position of the channel on the cradle:
 - the bottom face of the plate in the x-z plane was constrained in all directions and rotations using an Encastre boundary condition.
 - the top face in the x-z plane was constrained directionally and rotationally in the z-direction.
- Load:
 - the top face in the x-z plane was partitioned evenly into three equal parts.
 - the pressure load from the recorded test data was applied to the corresponding left, middle and right part of the top face of the x-z plane.
- Material used: 95-15 Stainless Steel.
 - Material property data was obtained from in house testing.

- To insert a crack into the model:
 - Create a planar shell with dimensions needed for desired crack size (Part Module).
 - Translate the crack instance to desired location, making sure that it doesn't correspond to an element edge.

Example of a Crack in Finite Element Mesh

- Two pre-cracked models were used for XFEM simulation:
 - Case (1): a crack 0.015 x 0.011 inch horizontally along the gouge cut.
 - Case (2): a crack 0.015 x 0.011 inch vertically along the gouge cut.
- These pre-cracked models were done based off the results of a fluorescent penetrant test performed at YPG on 11 June 2011 that showed the presence of a 0.015 inch crack in the tooling defect area.

Applied Pressure Data

III.a. Method – Fe-Safe: Material Property and Load Data

- Analysis was performed using Fe-Safe version 6.2
 - Analysis type: imported dynamic explicit Abaqus analysis
- Material Used: SAE 4140
 - Ultimate tensile strength: 156,060 psi (very similar to 95-15 SS)
- Load Settings:
 - Step 1 at time = 0.2s, peak stress = 154,719, load scale: 0, 1; repeats = 5 (to simulate the reverberating from gun launch)

III.b. Method – Fe-Safe: Analysis Summary

$$i = 0, 1, 2, 3$$

- Analysis was performed using NASGRO version 5.0
- Model used was surface crack plate specimen (SC17) with the same dimensions as the plate measured in Abaqus
 - Model was chosen after consultation with J. Cardinal (staff engineer at SwRI)
- Materials: 95-15 Stainless Steel (from in-house testing) and 15-5PH H1025 Stainless Steel (defined in NASGRO)

5		
6		
7		
8		
9		

Distinct block case repetition table:

Block case	Times to apply
1	1

Schedule title [optional]

of times to repeat schedule

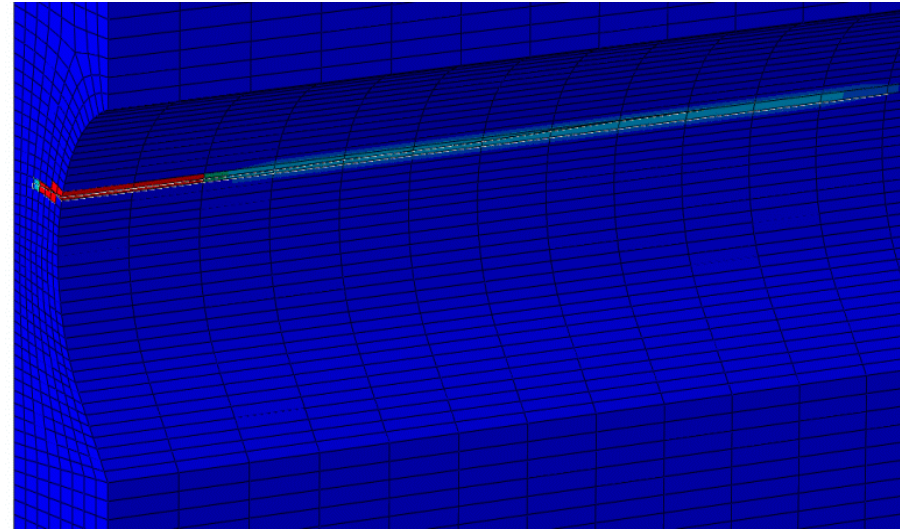

- Screen shot of build schedule; each load block is applied 1 time for 1000 cycles.

- The crack grows along the x-direction and varies between one and three elements through the thickness of the y-z plane.
- Value of 0.4 shows partial or surface cracking, not a complete through crack.

Crack at t=0s

Crack at t=1s

- The crack grows along the x- and z- direction.
- Crack propagation is similar to the crack initiation case.
- Crack is partial or surface cracking, not a complete through crack (based on the color values).

Crack at t=0s

Crack at t=1s

- The crack grows along the x- and z- direction; no crack growth in the y-direction.
- Crack propagation is not similar to the crack initiation case.
- Crack is partial or surface cracking, not a complete through crack (based on the color values).

- Crack initiation occurs at a Von Mises stress of 144,562 psi, which is slightly lower than the yield stress of the material
 - As the crack continues to propagate yield stress is reached
- Plastic strain was not exceeded

Analysis completed

FEA Fatigue Analysis and export of results completed with no errors or warnings.

Worst Life-Repeats	1071.369	Element 31152.1
Largest(+ or -) SMAX/Yield	1.218	Element 30567.1
Largest(+ or -) SMAX/UTS	1.093	Element 30567.1

[View log](#) [Close](#)

- Analysis shows a life cycle of 1071

- Results show that crack becomes unstable after 106 cycles
 - Crack grows to 0.072-in before failure, which is almost the thickness of the part.
 - Part thickness is 0.080-in

Conclusions:

- Results from all three methods show that the plate specimen fails the reliability requirement of 1100 mean rounds.
- The plate specimen was not able to prove that the channels with the tooling defects would survive the required amount of firings/cycles.

Path Forward (suggested):

- Since the plate specimen was not able to prove survivability, a more accurate FEA model needs to be analyzed in Abaqus and fe-safe to determine of the firing mechanism plate/channel would survive in the cradle assembly.
