

Integrated Model Framework for Concept Development

THE VALUE OF PERFORMANCE.
NORTHROP GRUMMAN

2014 NDIA SE Conference

October 29, 2014

Christopher Hoffman
NGES Systems Engineer

Today's Outline

Today, I will discuss Model Based Engineering

Using a developed "Integrated Model Framework"

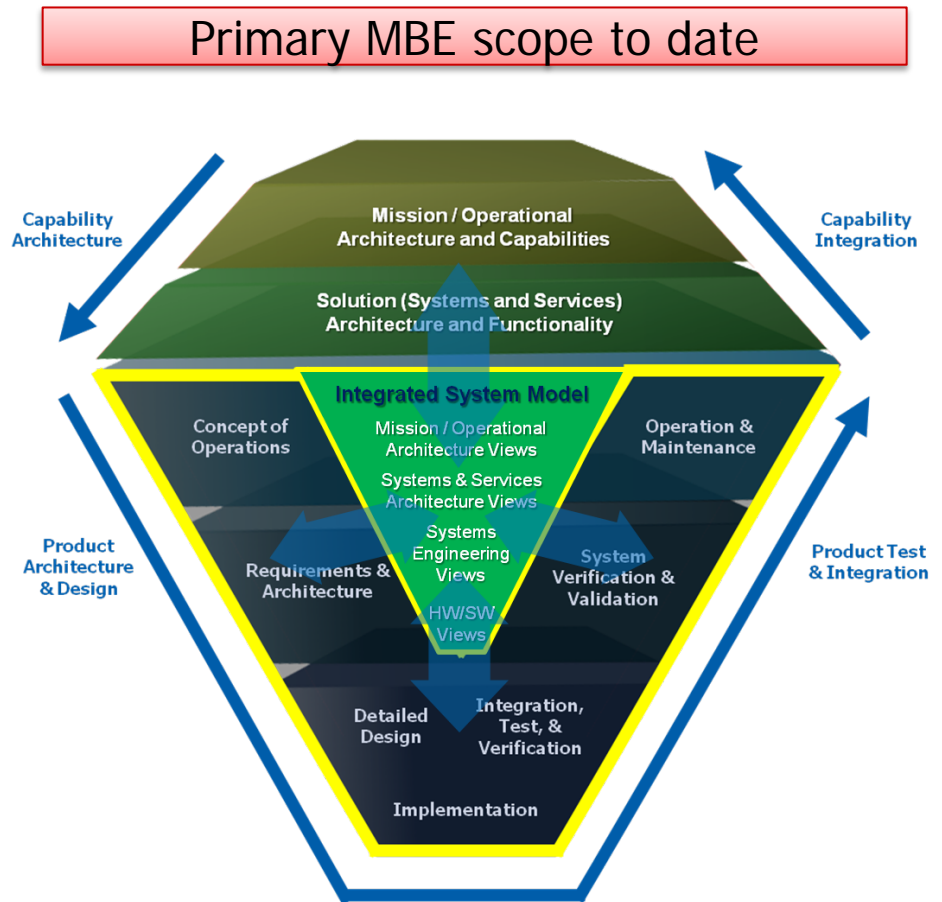

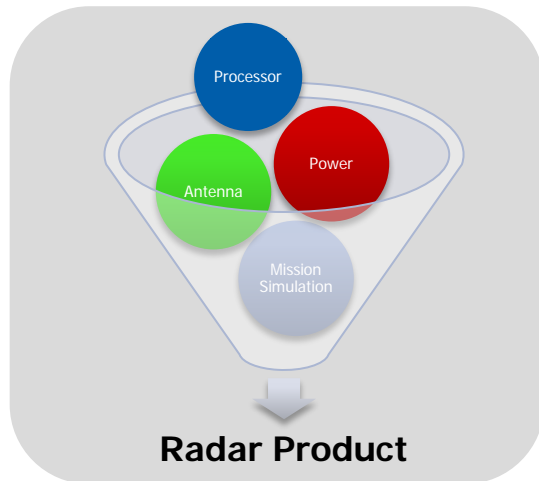

How a Descriptive to Analytical Model approach

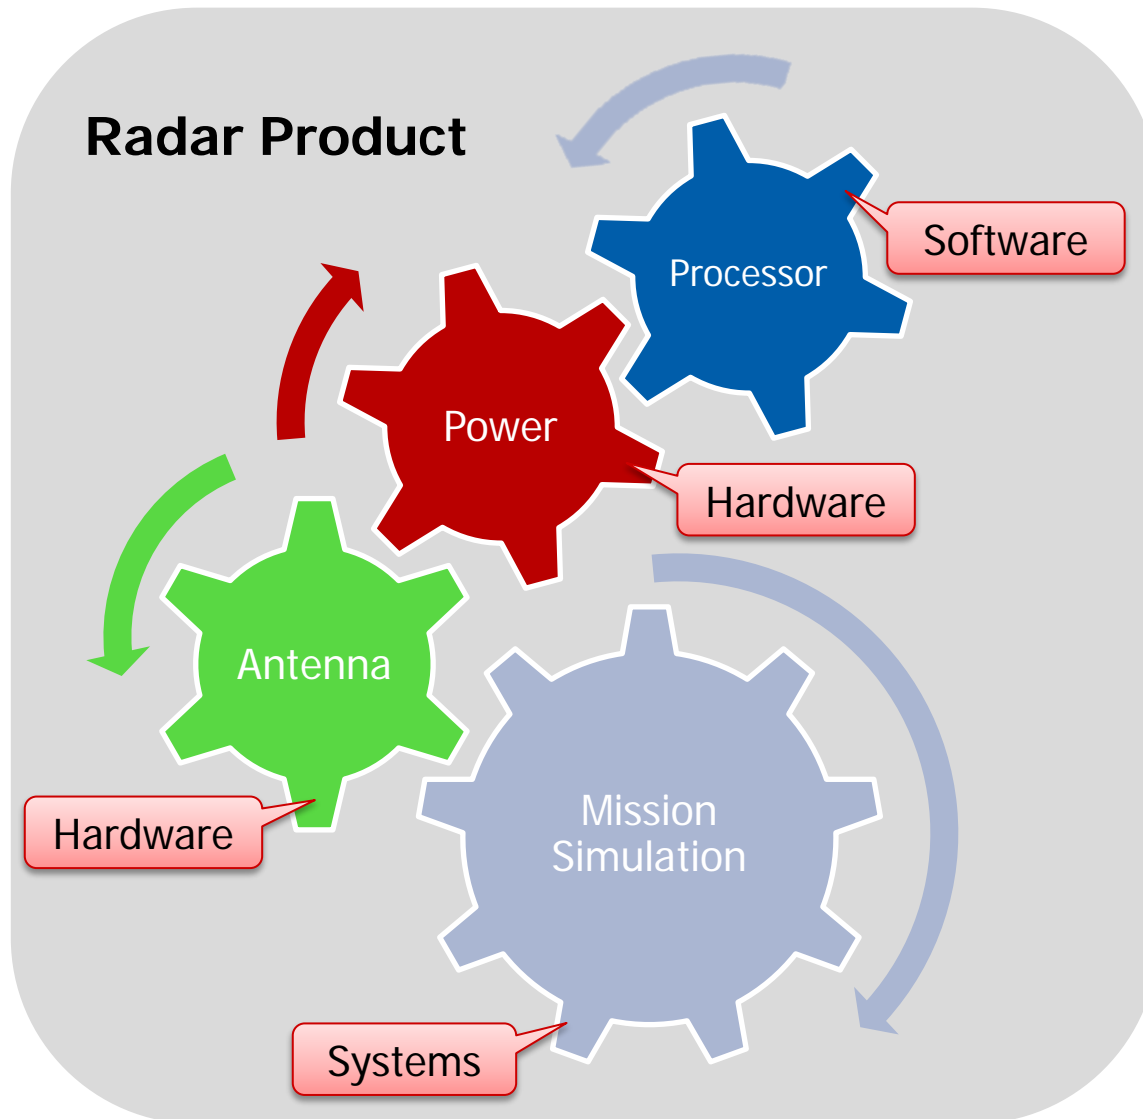

Using existing disparate models

Can validate architectural choices quickly, efficiently, and optimally

How can Model Based Engineering (MBE) be implemented on a program?

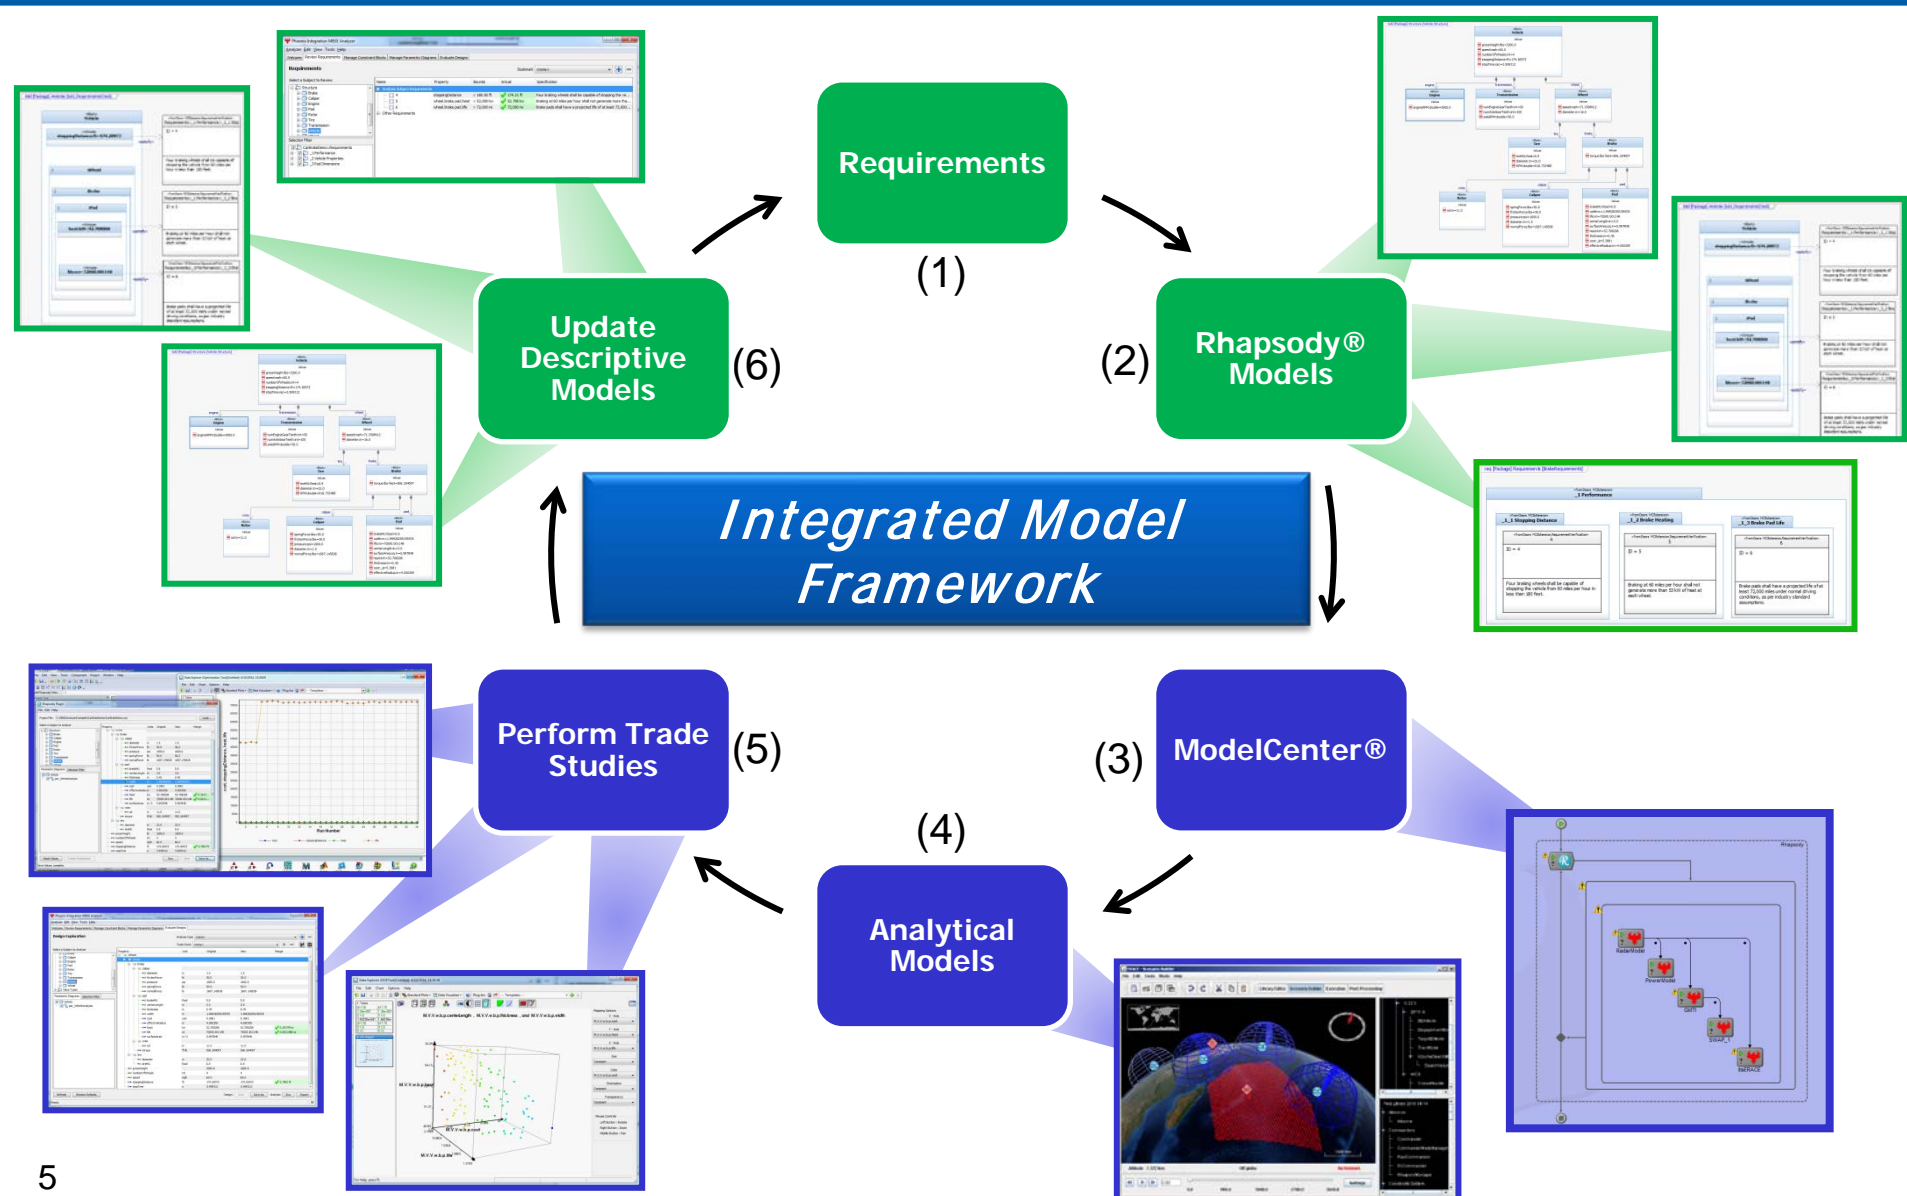

- Many use MBE successfully today...
 - Solving hard problems
 - Finding new novel solutions
- Unfortunately, most have been stovepiped...
 - Models are typically limited to a discipline, limiting the trade space

- The Mission Systems Engineering group at Northrop Grumman decided to take the next step
- 6-Step process for integrating models
 - “Integrated Model Framework”
 - Phoenix Integration’s MBSE Pak®
- Will integrated models enable better/quicker system level decisions?

Integrated Model Framework: Descriptive to Analytical and Back

Investigating Radar Performance vs. Cost Over a Variety of Generic Platforms

Helicopter

- Altitude
- Weight
- Speed

Large Aircraft

- Altitude
- Weight
- Speed

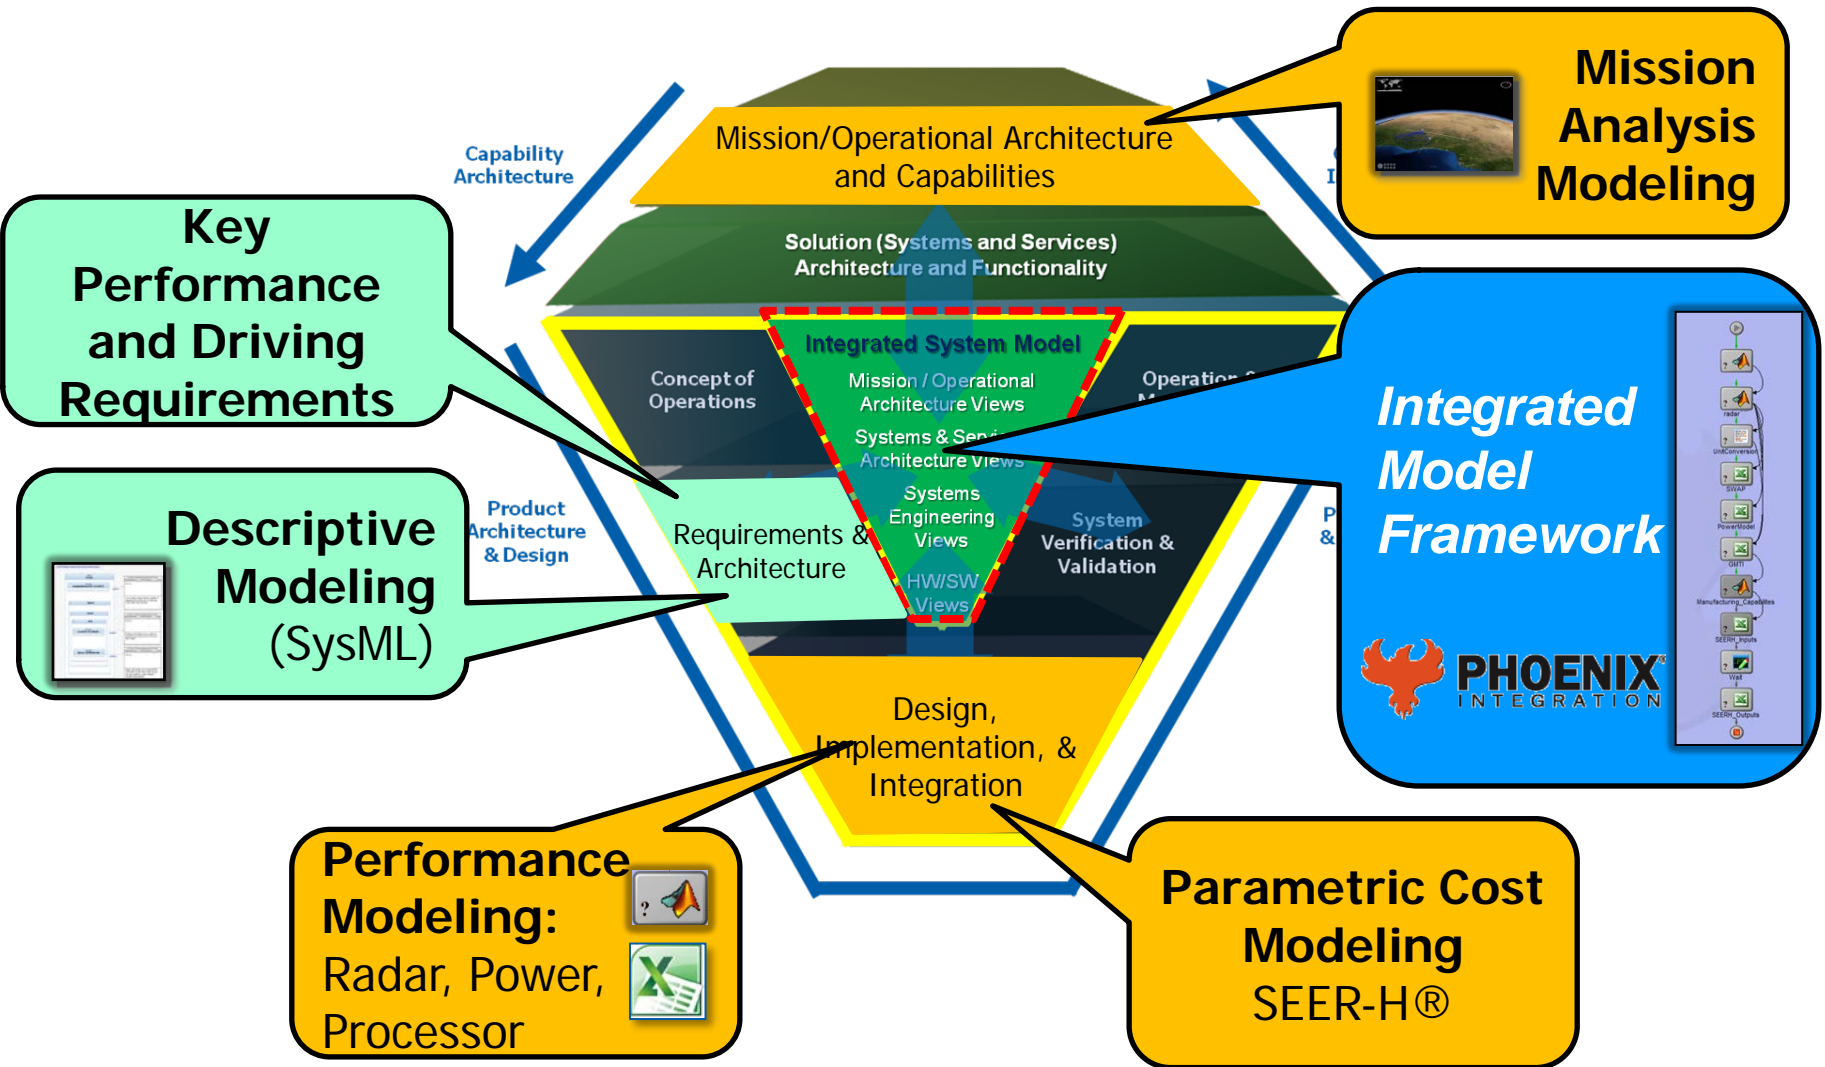

Fighter Jet

- Altitude
- Weight
- Speed

Utilizing Disparately Designed Models to Perform Trade Analysis

System level models from different departments inherently share information

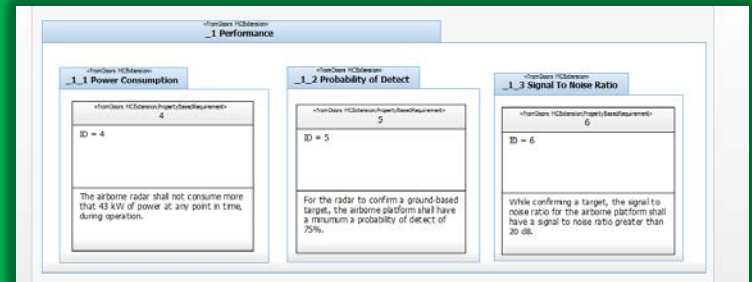

Step 1: Generate a Requirements Diagram

DOORS® or Excel® Requirements

- *Power Consumption*
- *Radar System Weight*
- *Probability of Detection*
- *Signal to Noise Ratio*

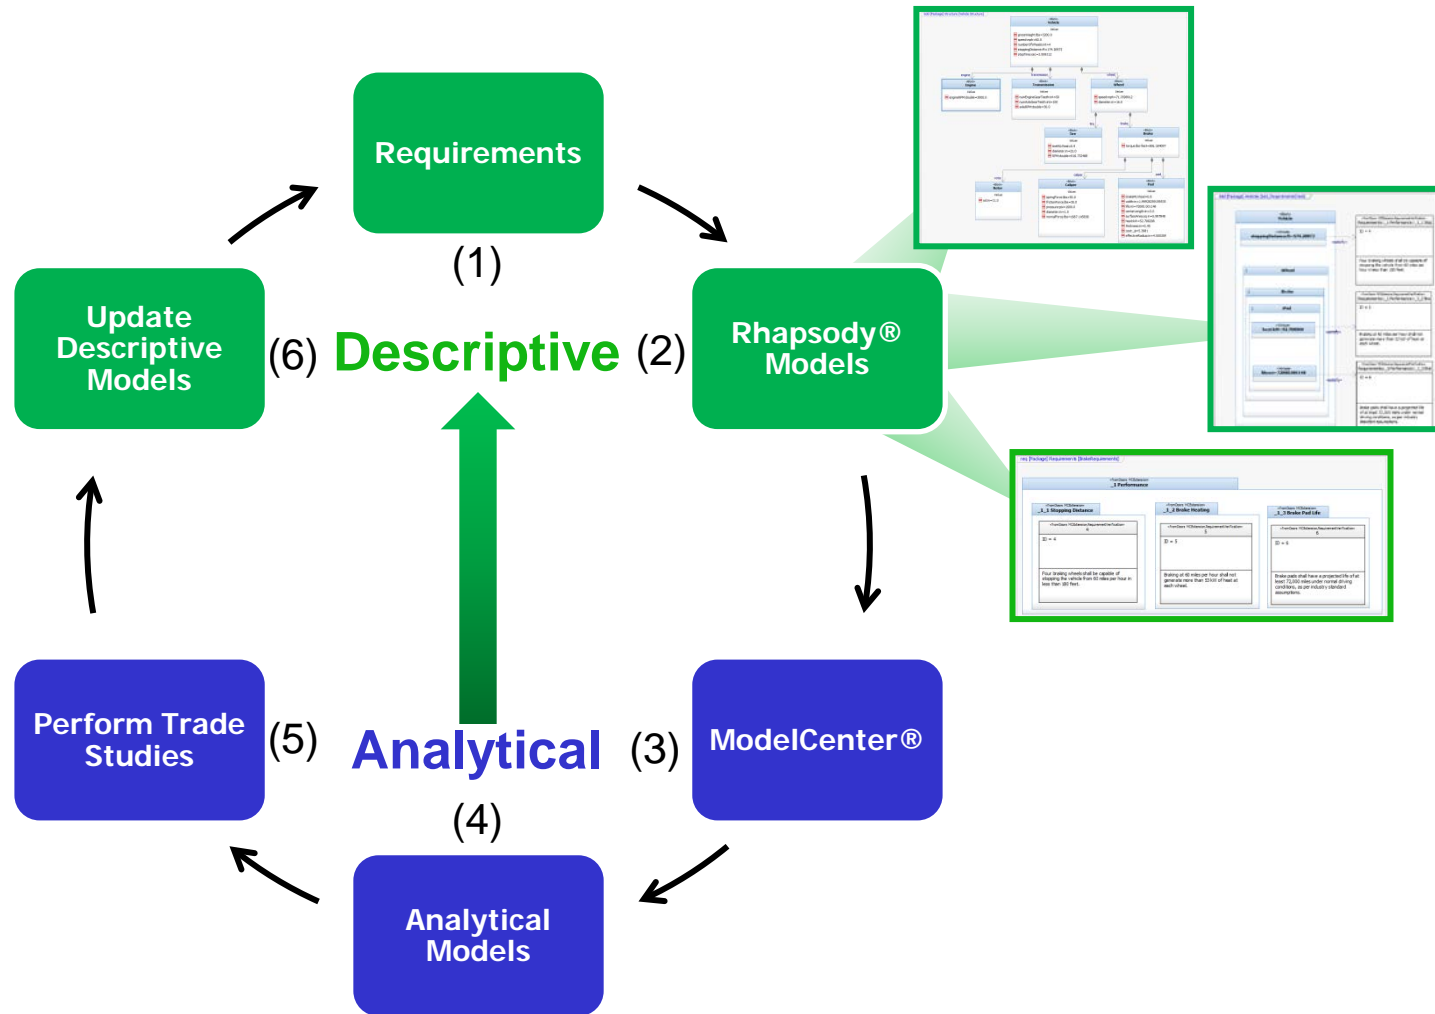

IBM Rational Rhapsody®

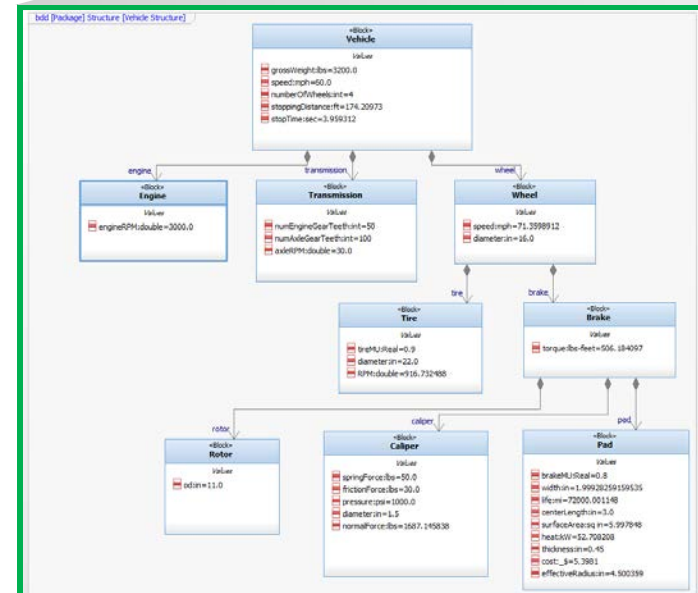

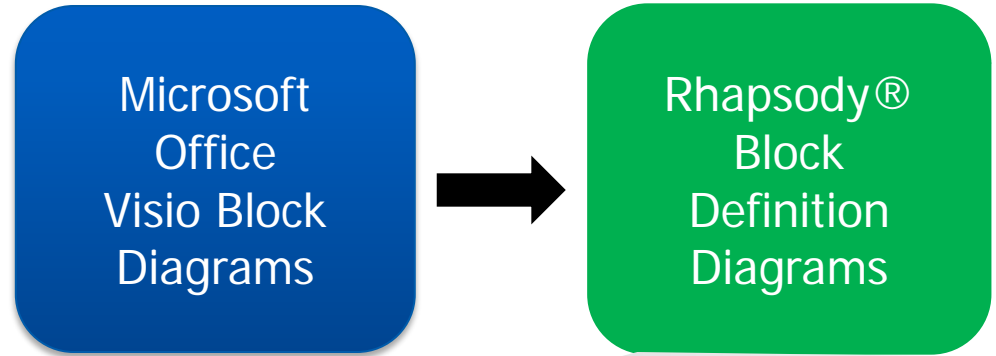

- Requirement Specifications brought into Rhapsody®
- Lower and Upper Bounds can be established in Rhapsody®
 - Requirement goals are established

Setting up the System Architecture

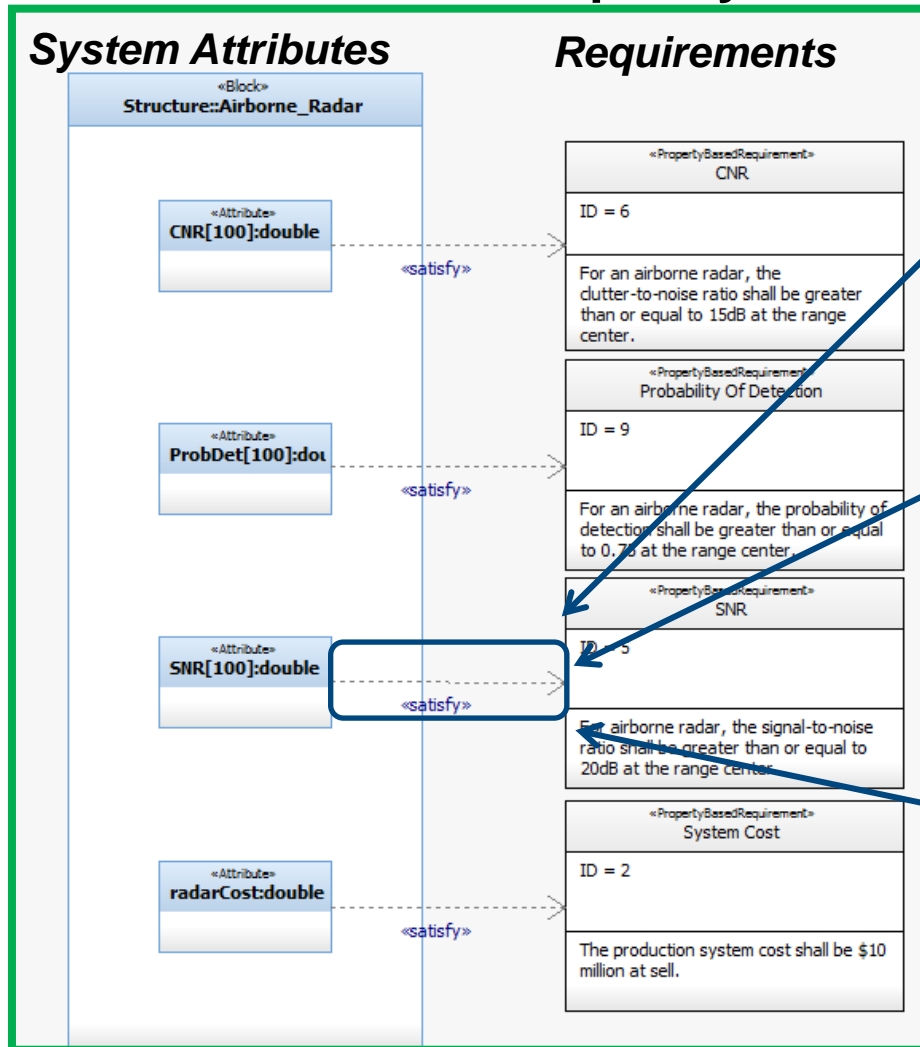

Step 2: Decompose Visio/Initial Block Diagrams to Rhapsody Block Definition Diagrams

- Generate an Architecture based on requirements
- Typically designs are created in Visio
 - Visio does not offer the traceability needed in this process
- Manually decompose Visio diagrams into SysML Block Definition Diagrams

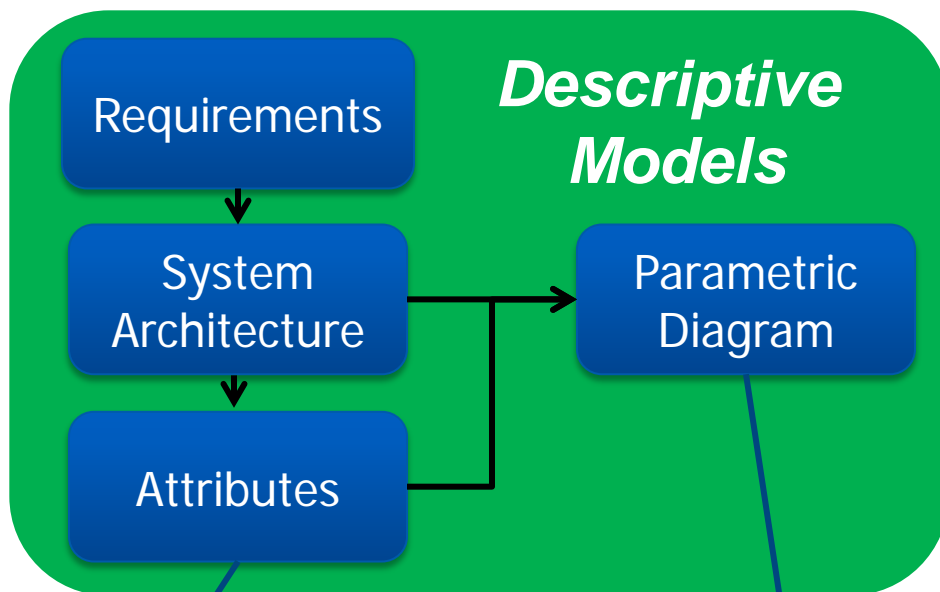

Step 2: System Architecture Connects to Requirements

IBM Rational Rhapsody®

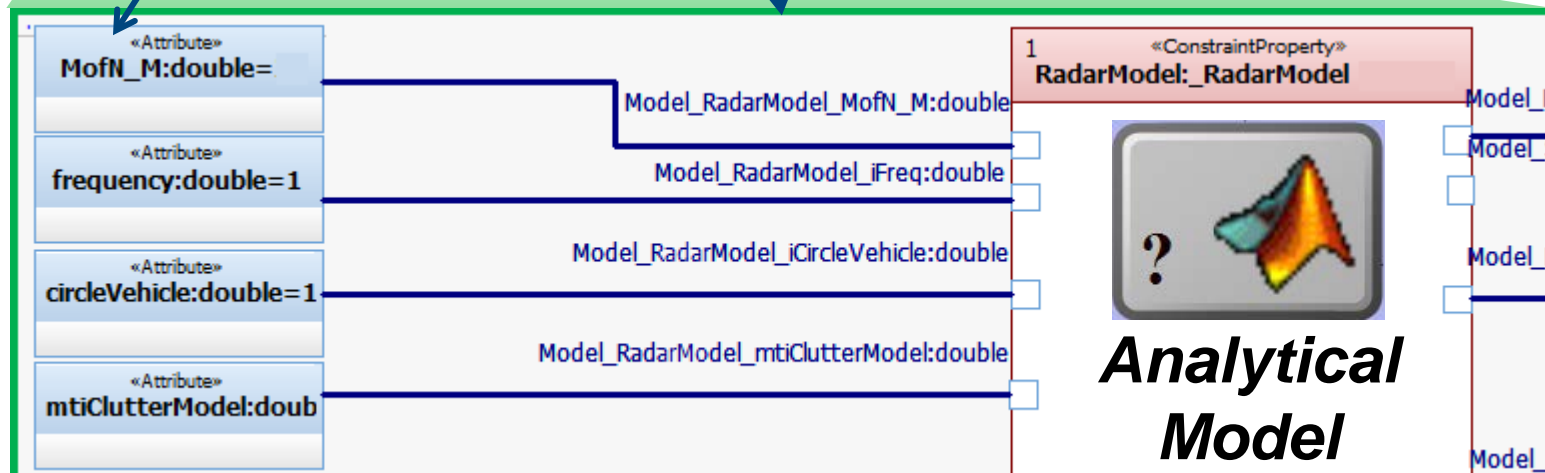

- Establish a connection between Requirements and System Architecture
 - Traceability
- Link attributes of system performance to Requirements
 - Clutter-Noise-Ratio
 - Probability of Detect
 - Signal-To-Noise Ratio
 - Radar Cost
- Satisfy Relationships are set up in Rhapsody

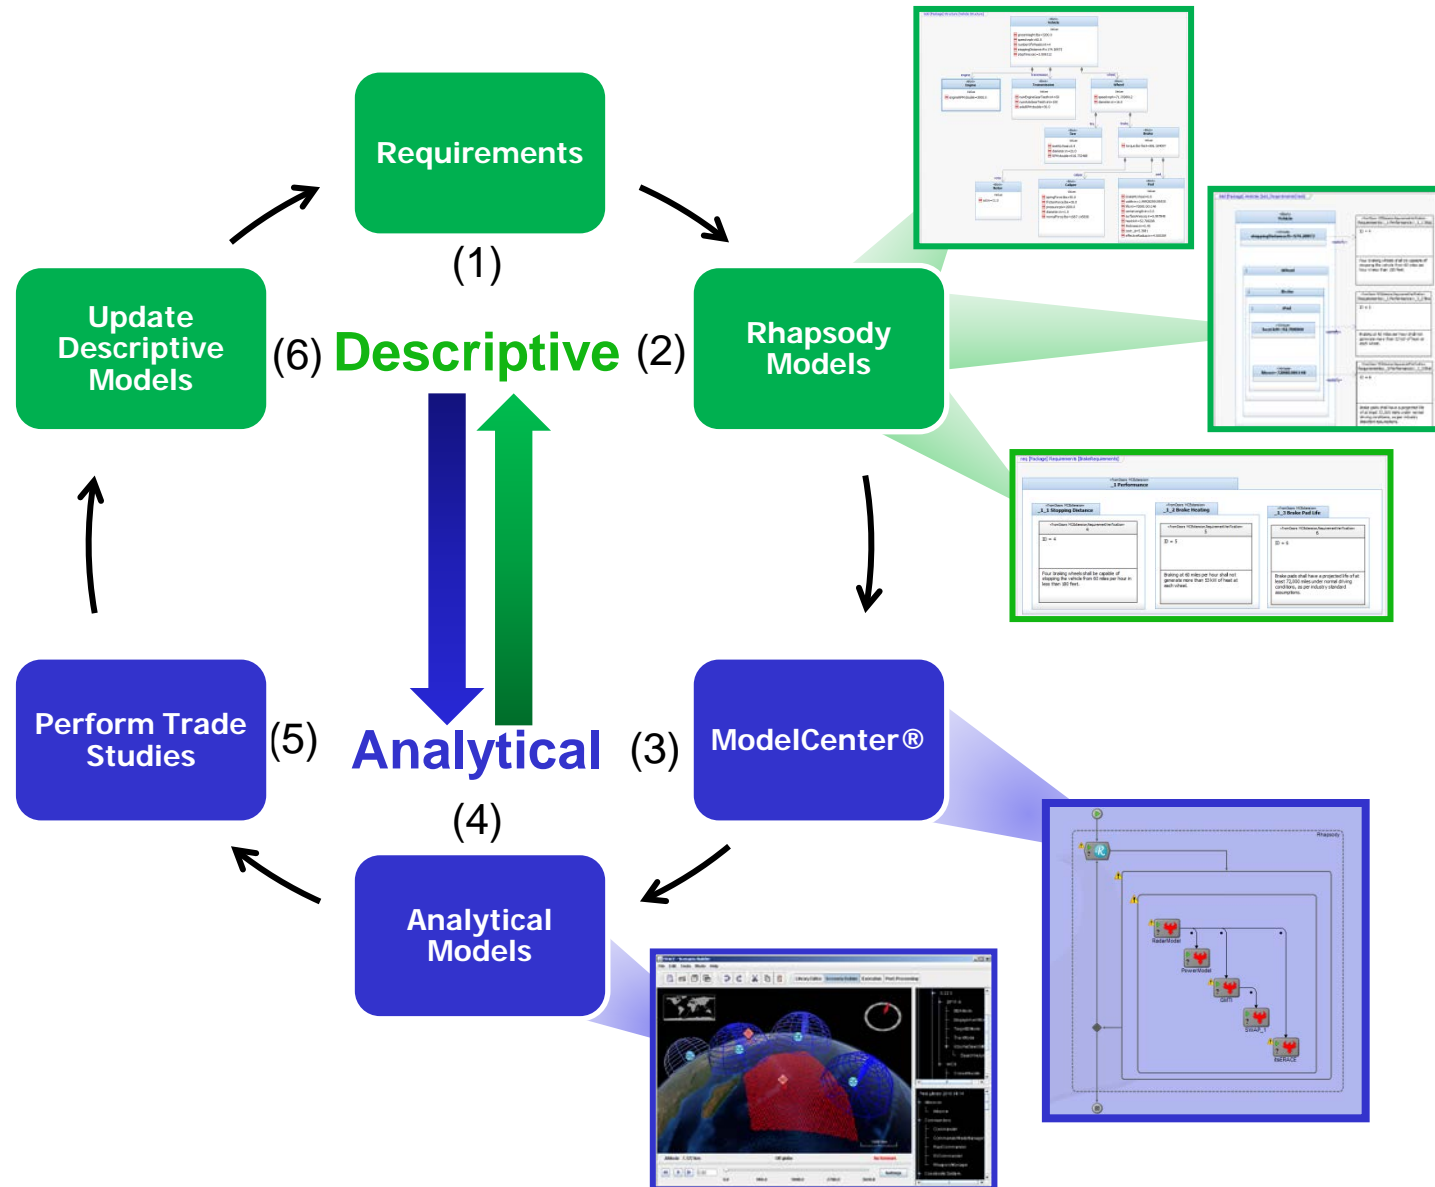

Step 2: Connecting Descriptive and Analytical Models

- Establish connections between attributes and Analytical Models in a Parametric Diagram
 - Input performance parameters (attributes) connect to C++, Java, MATLAB, and etc. type models

Moving Between Descriptive and Analytical House

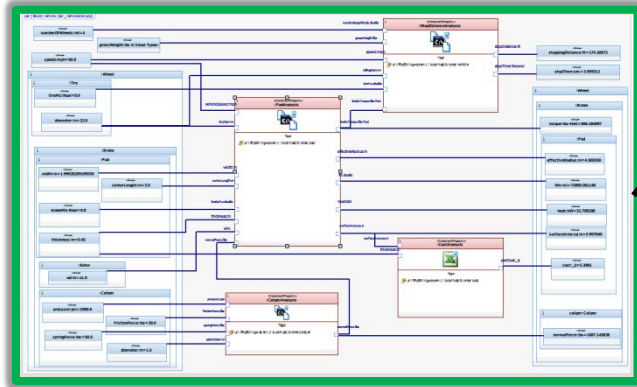

Step 3 & 4: Establish Connection Layer

ModelCenter® “Connection Layer”

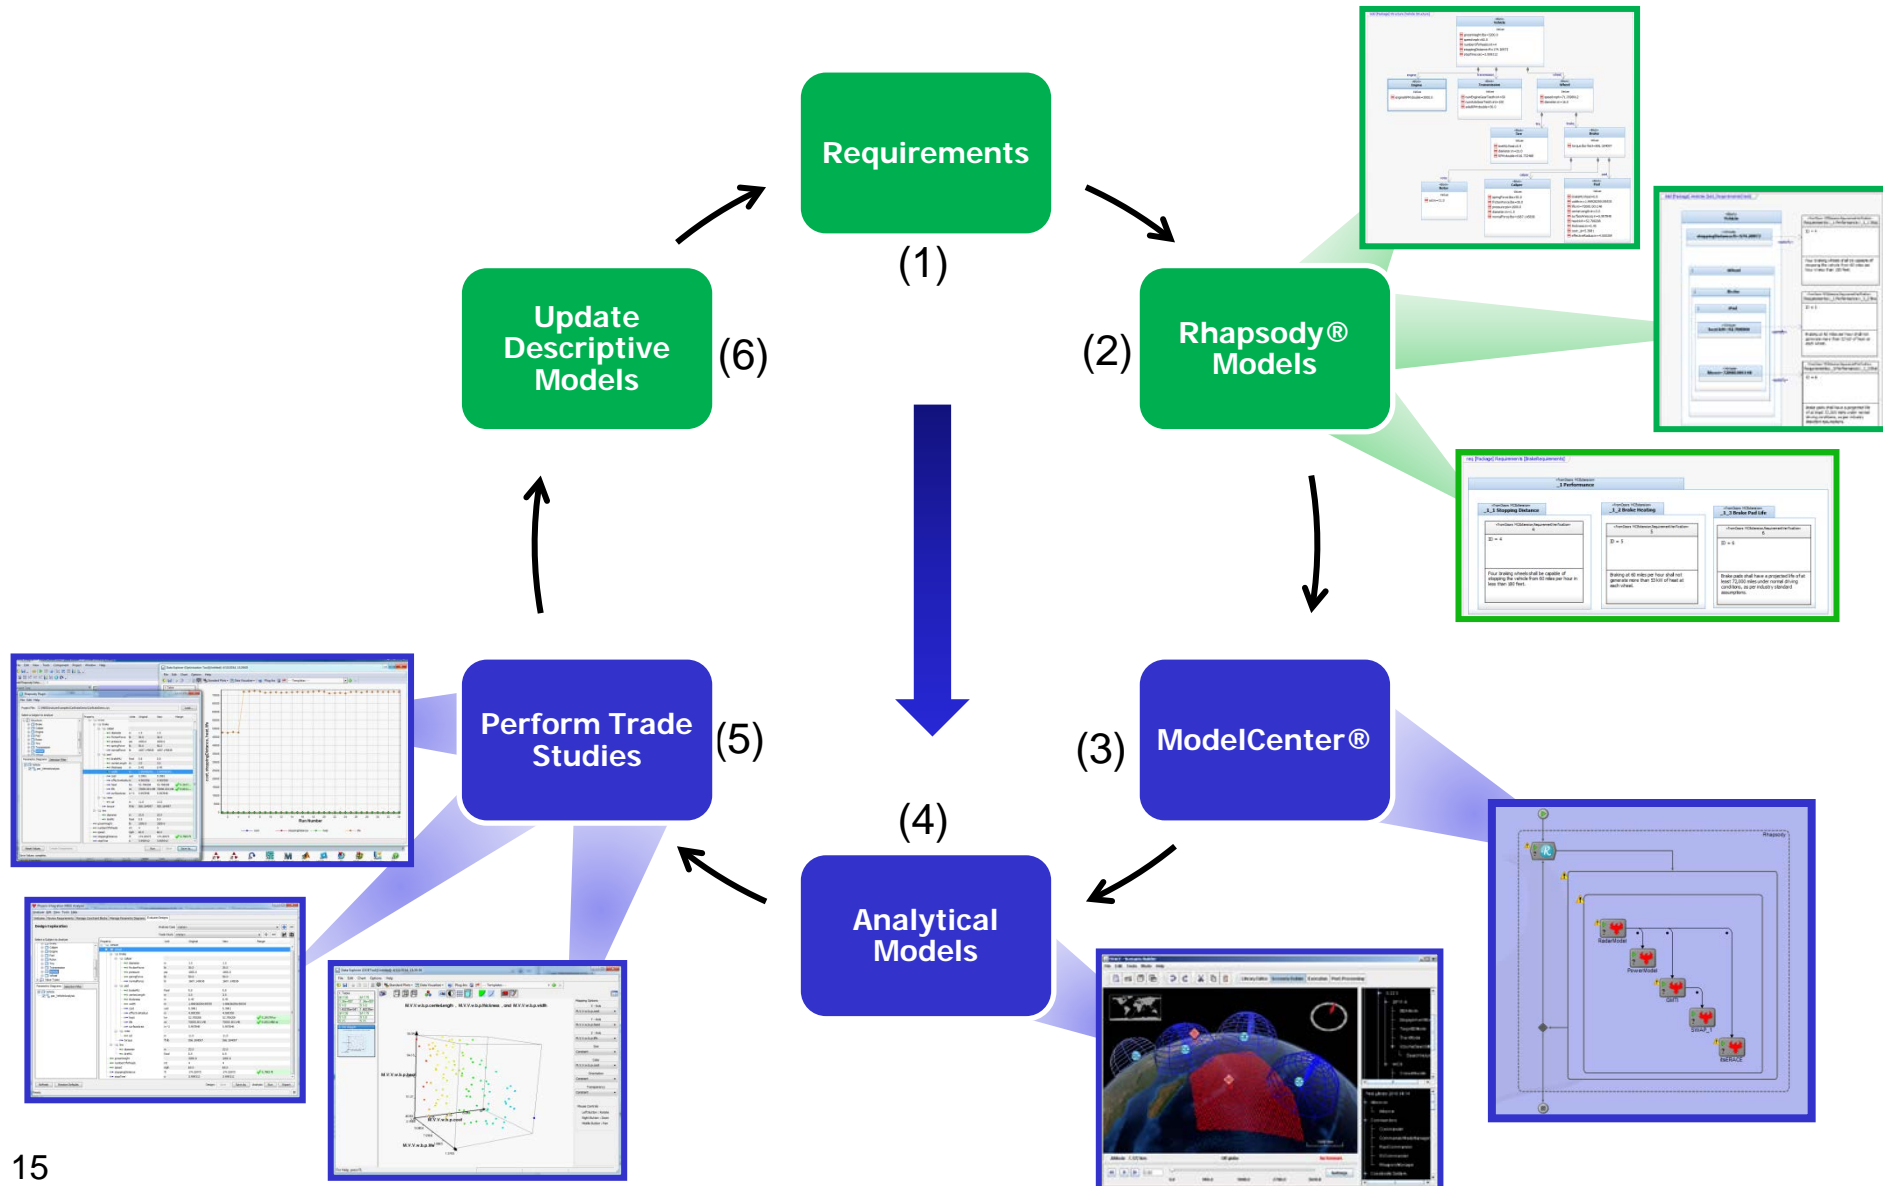

“Analytical Models”

Rhapsody® “Descriptive Model”

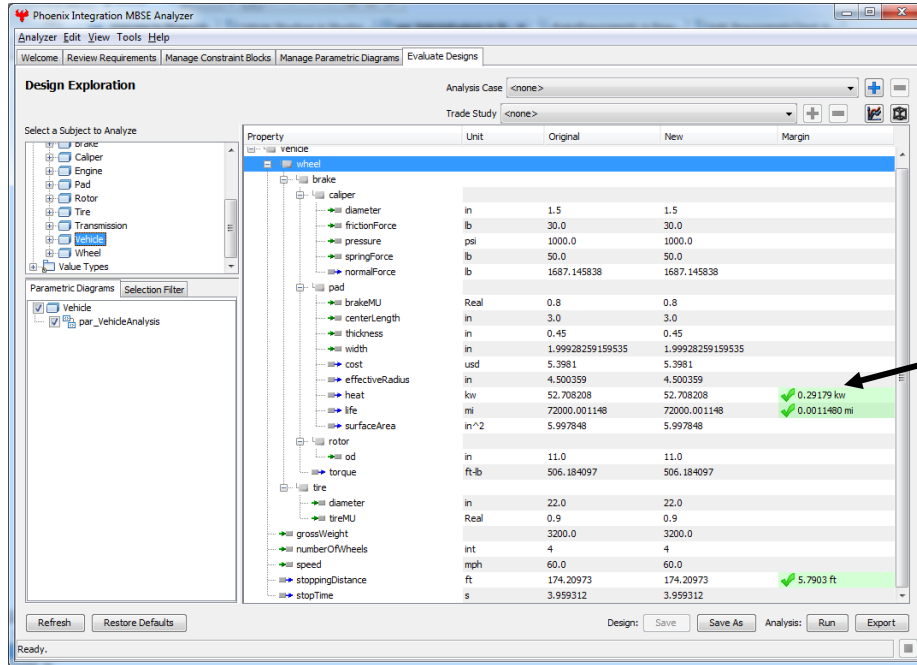

- Phoenix Integration’s MBSE Pak® will establish physical connections between Descriptive and Analytical Models
- After analysis is performed, ModelCenter® will flow data back to Descriptive Model

Integrated Model Framework: Perform Trade Studies

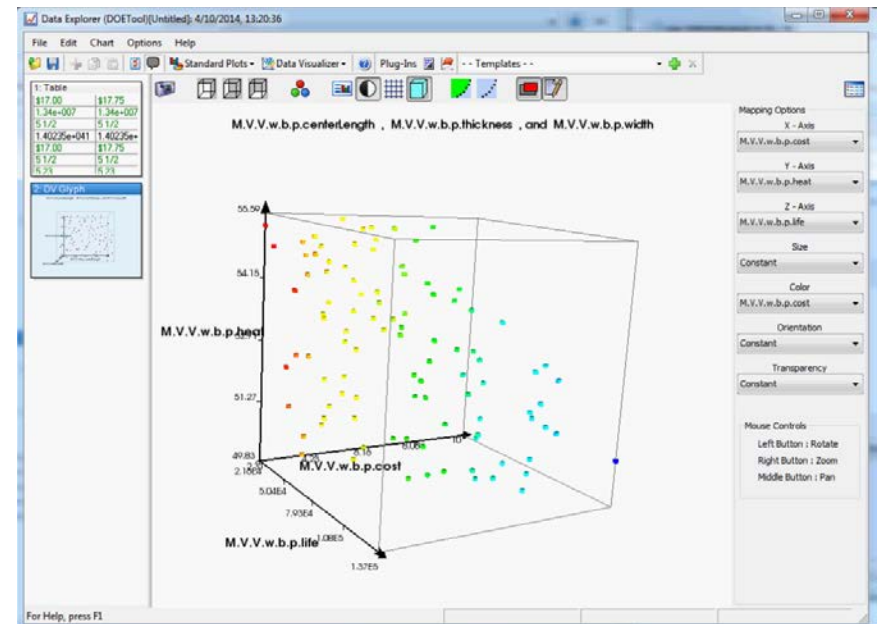

Step 5: Perform Trade Studies in ModelCenter

- Design of Experiments and Optimization Analysis
- Dashboards are created automatically for feedback of requirement verification

- Visual analysis of the data can be created

Cost and Performance Scaling of Varying Size Radar Options

- This simple experiment confirms logical expectation:
 - Bigger Radar yields Higher Probability of Detect at a Higher Cost
- Detailed analysis enables discussion of:
 - Can we achieve target performance within specific platform limitations?
 - What performance requirements drive solution cost and size?
 - How much is more performance worth?
- Able to evaluate more experiments along more dimensions using models integrated through ModelCenter® than ever possible manually

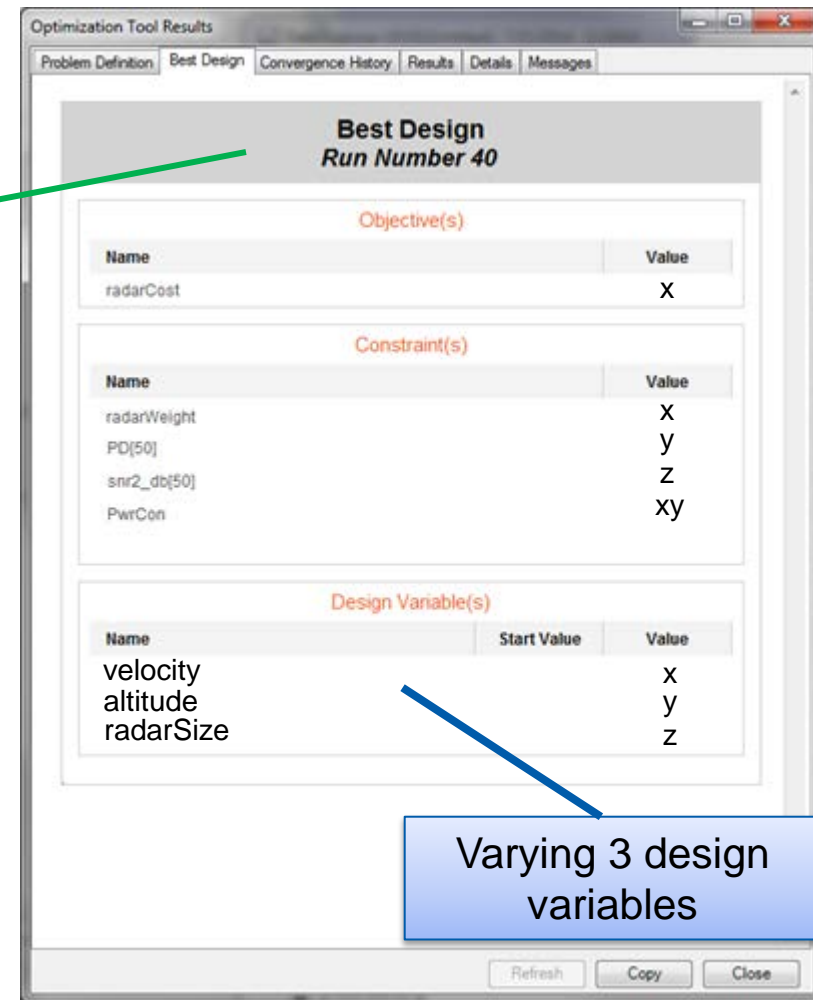

- Design Variables**
- 1) Altitude
 - 2) Radar Size
 - 3) Velocity
 - 4) Target Position

Color : Cost
- Red Higher Cost
- Blue Lower Cost

Trade Space Optimization to Investigate Optimal Designs

- ModelCenter® tries to leverage certain design variables by getting as close as possible to the constraints
- ModelCenter® suggests a best design (run 40 out of 86)
- Goal: Minimize Radar Cost
- Constraints are based on requirements

Running the Optimizer provides feedback about the models and flexibility of designs based on requirements

Higher Fidelity Cost Model Added: SEER-H Integration

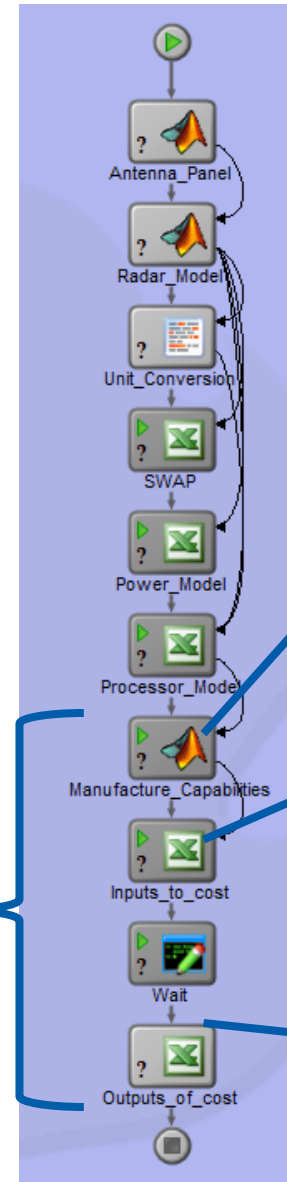

Color : Labor Prod Cost
- Red Higher Cost
- Blue Lower Cost

Color : Development Cost
- Red Higher Cost
- Blue Lower Cost

- Higher Fidelity Cost Model allows us to look beyond the material cost

SEER-H

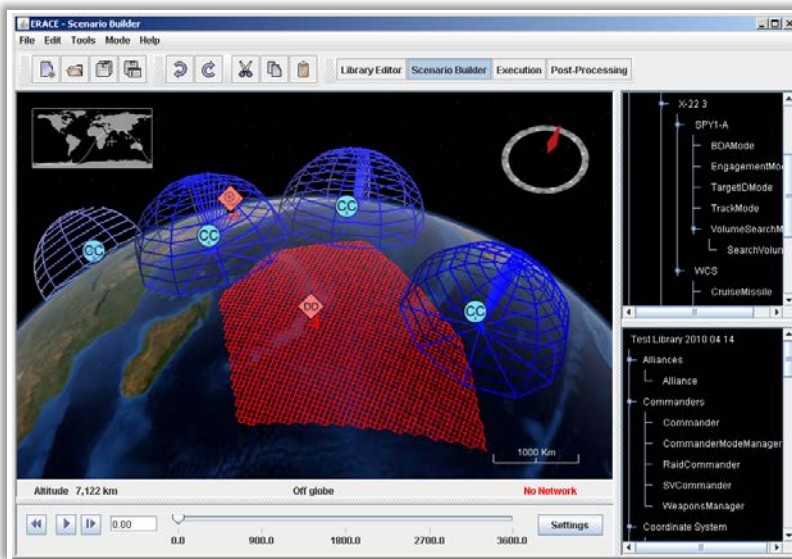

Logic for Manufacturing Capabilities

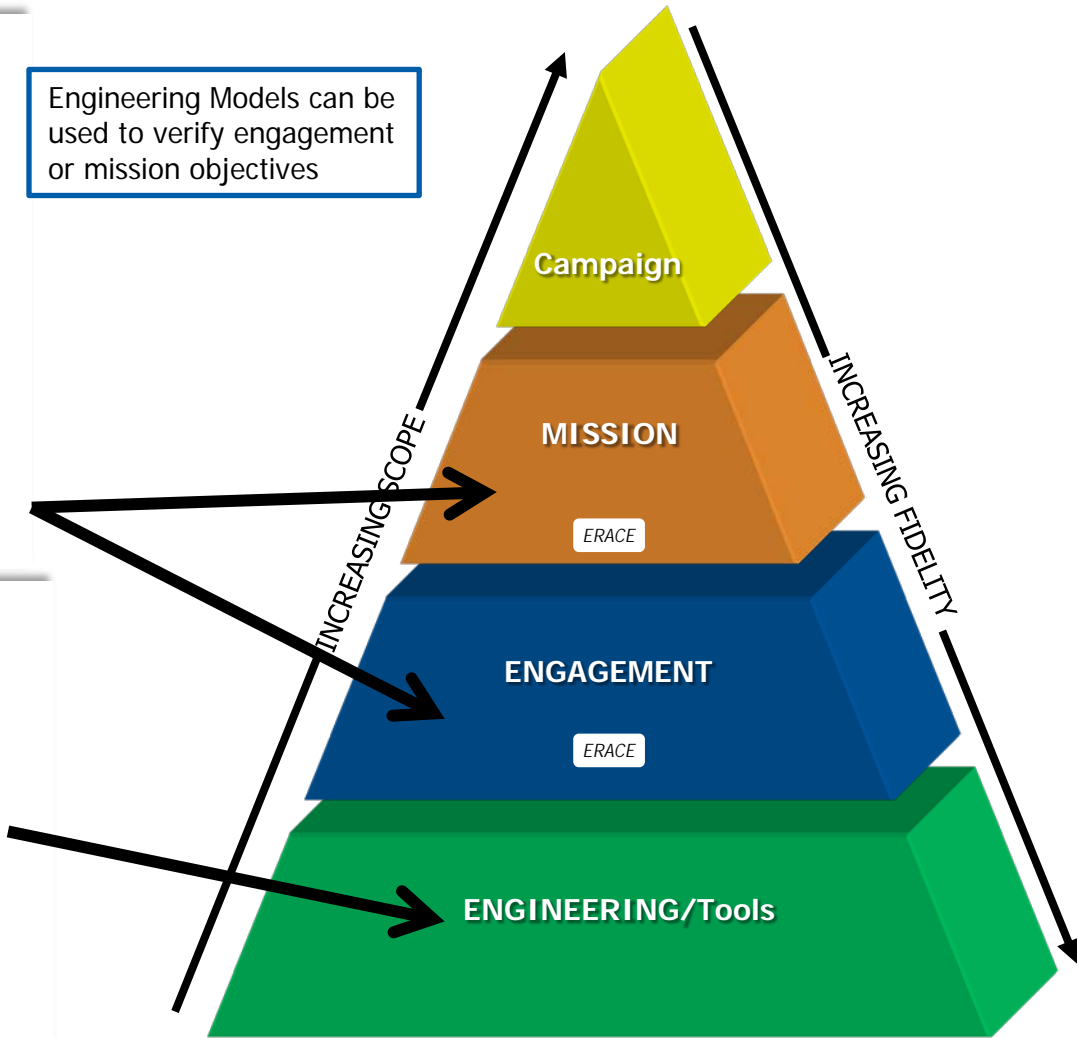

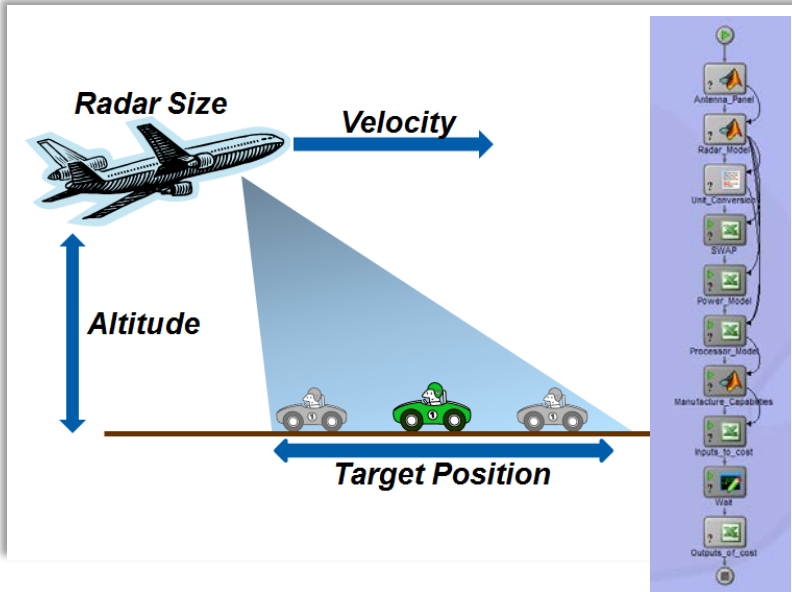

Quantity Produced

Production, Development, and Labor Costs

Mission/Engagement Simulation Validation: Enhanced Radar Centric Engagement Model

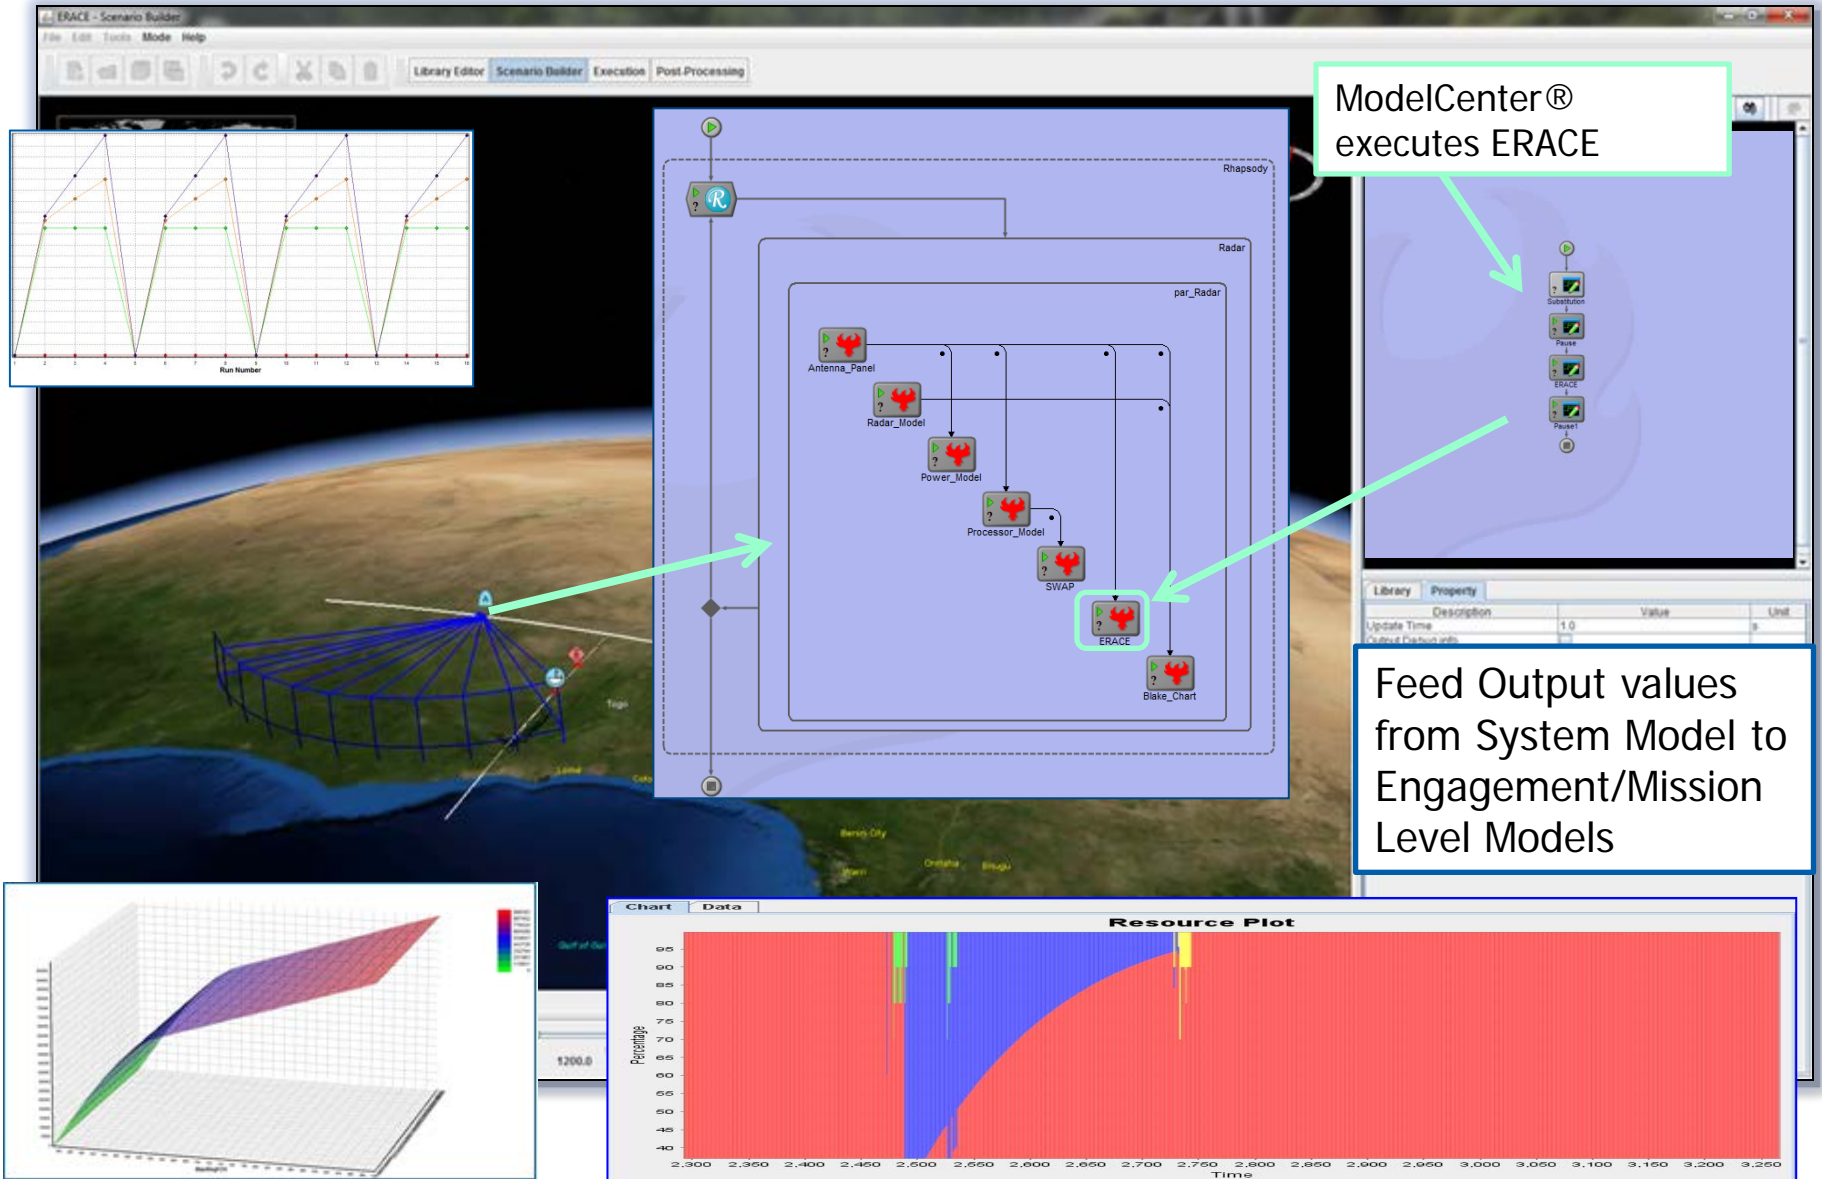

Engineering Models can be used to verify engagement or mission objectives

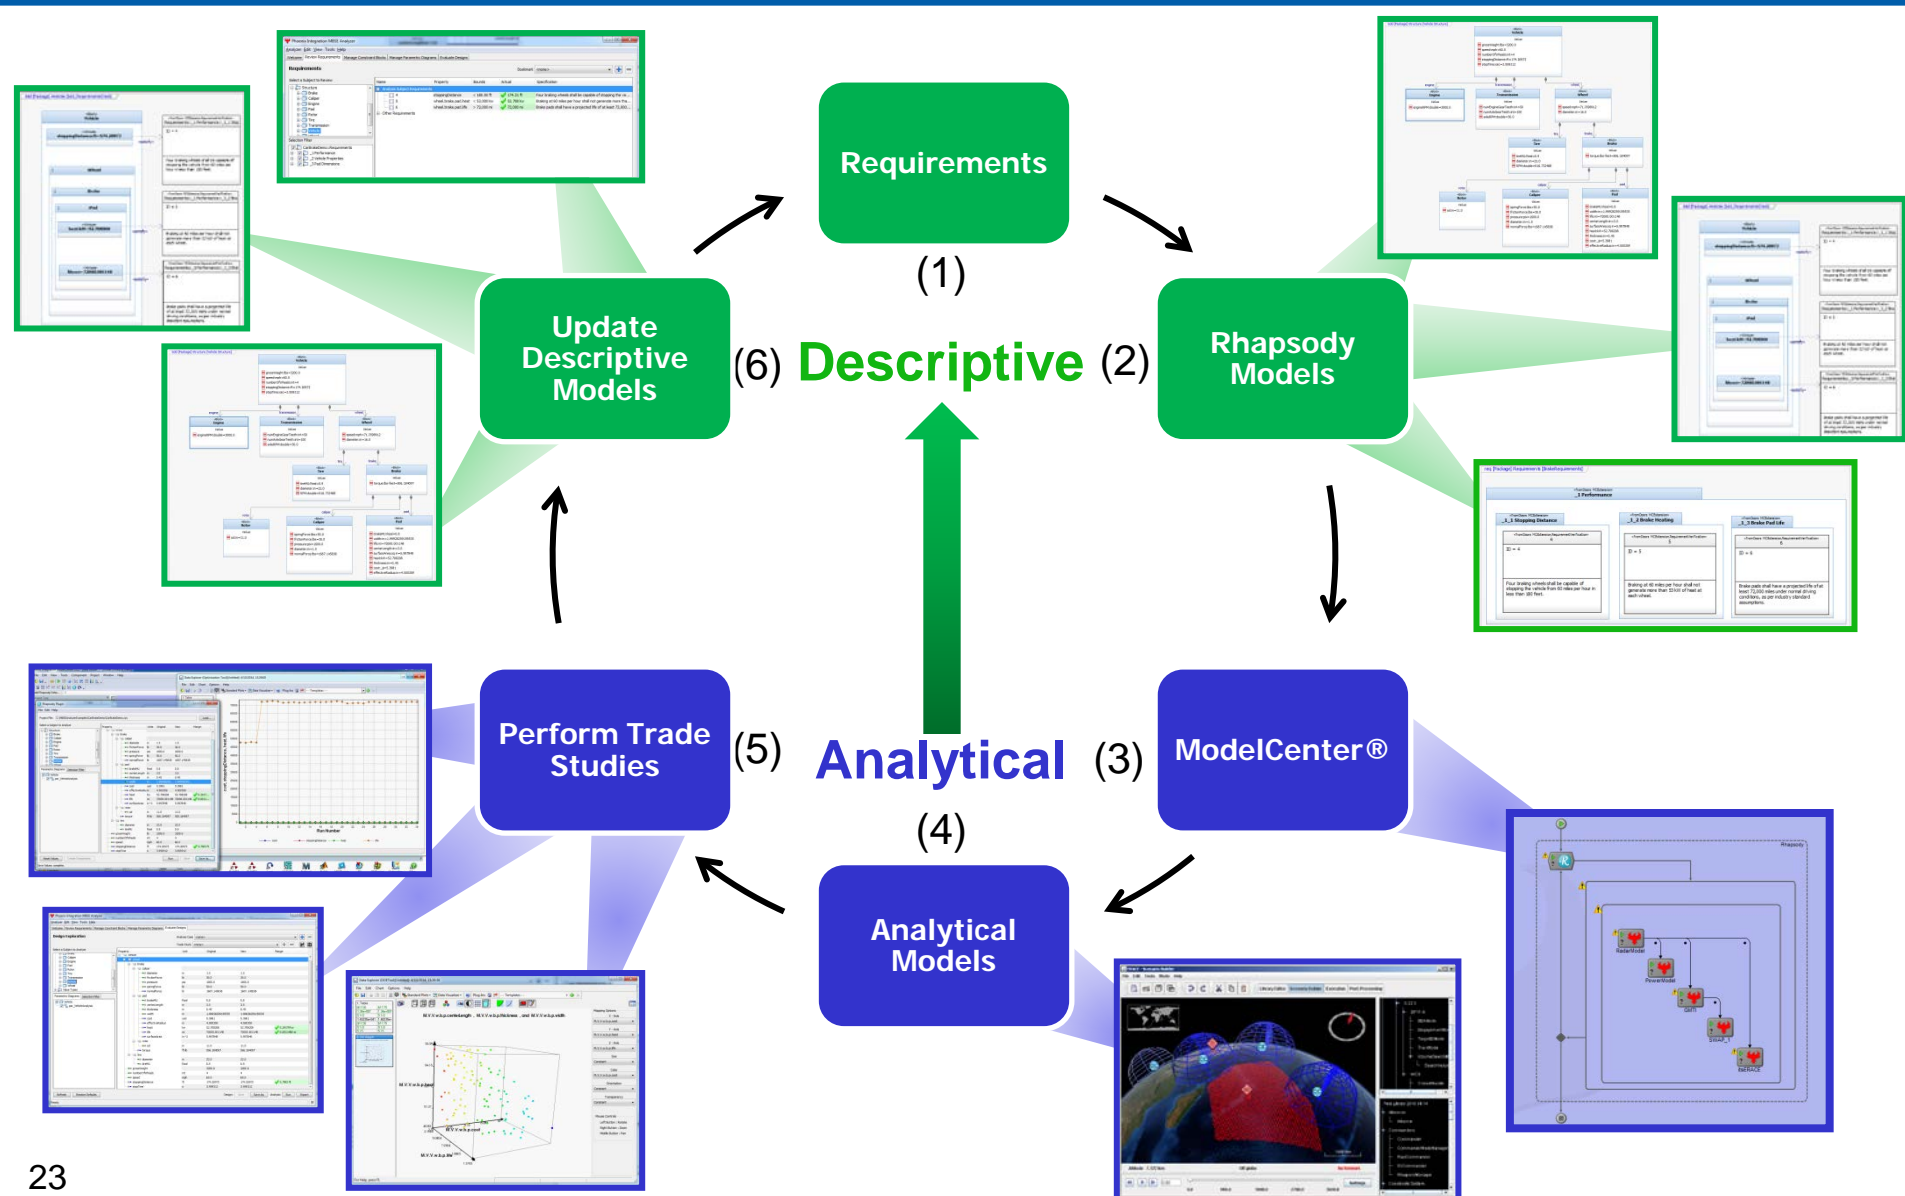

Validate system level parameters in an Engagement/Mission by increasing the scope

Integrate ERACE with Engineering Models

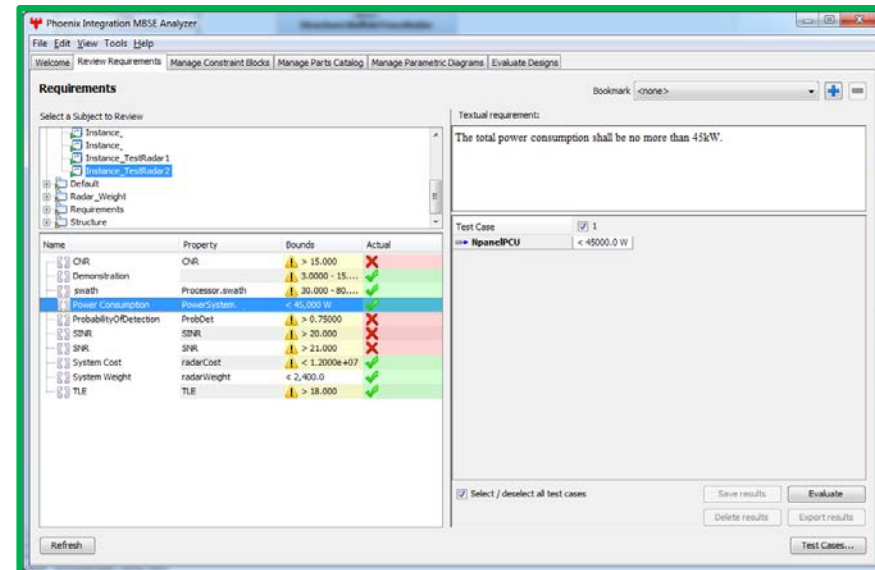

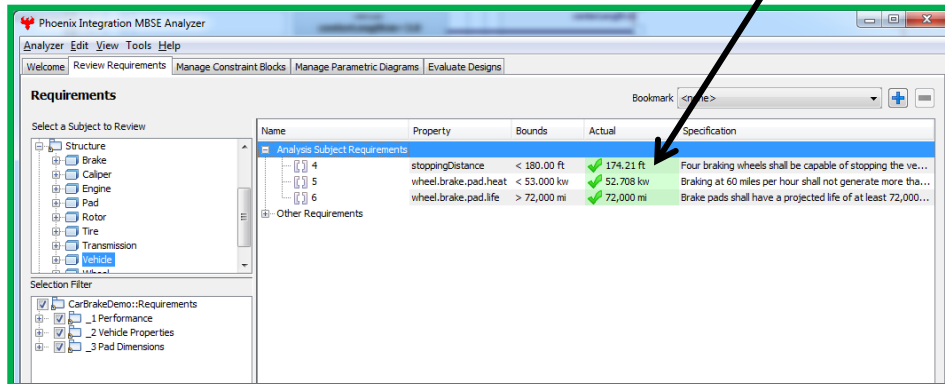

Analytical Back to Descriptive: Update Architecture with New Attribute Values

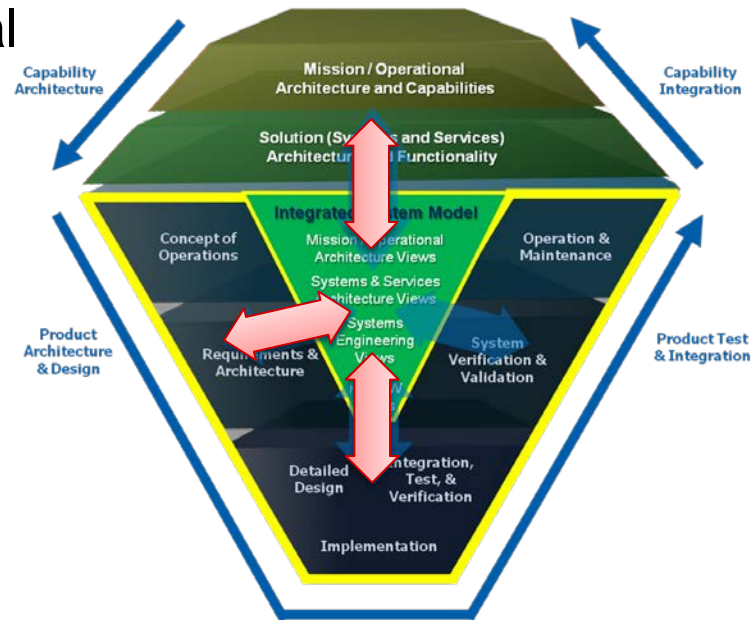

Step 6: Update Descriptive Model with New Design Variable Values

- Design parameters (attributes) have changed due to trade studies performed
 - Rhapsody “Descriptive Model” is updated with new attribute values
 - New parameters show where current architecture fits with performance requirements

Getting Ever Closer to the End-to-End Model

- **Linked** requirements and architecture (descriptive modeling), with engineering and engagement/mission models (analytical modeling)
- **Generated** vast quantities of trade studies to perform cost vs performance analysis
- **Reduced** manual communication between teams
- **Paved** the way for validating engineering design decisions with respect to the customer's mission

THE VALUE OF PERFORMANCE.

NORTHROP GRUMMAN

Christopher Hoffman is currently in the Professional Development Program as a Systems Engineer for Northrop Grumman Electronic Systems (NGES) in Baltimore, MD where he has worked for the last year. Prior to working at NGES, he worked for an organization designing and building micro and nanosatellites for the Air Force Research Labs in Boston, MA. He received a Bachelor's of Science in Electrical Engineering at Boston University in 2013 and is currently finishing a Master of Science degree in Electrical Engineering at Johns Hopkins University. Since joining NGES he has worked in the Power Conversion Technology group designing and testing power supplies for future radar designs and is now part of the Mission Systems Engineering group tasked with implementing Model Based Engineering practices on internal programs.

As systems become more complex, turning the many knobs on design choices becomes a complex n-dimensional problem. Not only is this difficult from an analysis point of view but it is further inhibited by the amount of communication needed between different system designers. Because of this, it is easy to optimize a portion of the system at first, say an antenna, but later find that the rest of the system components (power, physical structure, and software design) are now all constrained. Flexibility in both design and cost are now lost and the ability to change designs in the future are timely and expensive. Alleviating the stove piping effect of designing complex individual components for large systems throughout concept development is a must.

An integrated model framework was implemented for an internal customer, generating large amounts of trade studies by connecting architectural models with integrated software, antenna, power, and cost models for a radar design. What came out of this implementation was the ability to cut down on the labor and time required to combine data from independent models from many disciplines. This opened up the possibilities of turning new and more knobs of designs that would not have been considered due to the stove piping of information.
